[1] The Council's office is at 50, Merrion Square, Dublin.

University of Otago

Next February, at the age of 70, Sir Charles Hercus will be giving up his post as dean of the Otago *Medical School* He is to continue part-time work as medical secretary to the New Zealand Medical Research Council Dr Edward G Sayers, C M G, consulting physician in Auckland, has been appointed to succeed him

Dr Sayers qualified in Otago, and after postgraduate study in London worked as a medical missionary in the Solomon Islands He returned to Auckland to practise as a physician before the war, in which active service took him to various theatres, and he attained the rank of colonel He has recently retired from the presidency of the Royal Australasian College of Physicians, and he is a fellow of the London college and an honorary fellow of the American one He is chairman of the New Zealand Medical Council and serves on a number of committees in the Health Department dealing with specialist services Last year he visited Canada, the U S A, and Great Britain

College of General Practitioners

Dr E F Scowen will give the Pfizer lecture at 9 P M on Wednesday, Oct 15, at St Bartholomew's Hospital *Medical* College, London, E C 1 His subject will be Some Difficulties in Prescribing

British Congress of Obstetrics and Gynæcology

This congress will be held in Cardiff from July 14 to 16 under the presidency of Prof Gilbert Strachan The programme is to be published in November The congress secretaries may be addressed at the *Maternity Hospital*, Glossop Terrace, Cardiff

Nutrition and Teeth

The Nutrition Society will hold a symposium on this subject at the London Hospital Medical College, E 1, on Saturday, Oct 4 Further particulars may be had from Miss D F Hollingsworth, c/o Ministry of Agriculture, Fisheries and *Food, Great Westminster House, Horseferry Road*, S W 1

Space Medicine

The British Interplanetary Society, with the cooperation of the Royal Air Force Institute of Aviation Medicine, is to hold a symposium on this subject at B M A House, Tavistock Square, London, W C 1, on Oct 16 and 17 Further particulars may be had from the secretary of the society, 12, Bessborough Gardens, S W 1

Imperial Cancer Research Fund

The Fund has announced the following staff changes

Dr J Craigie has resigned his post as director of the Fund's Mill Hill laboratories so that he can devote himself entirely to research in the laboratories His advice on problems of research will thus continue to be available to the Fund

Dr R J C Harris is joining the scientific staff on Oct 1, 1958, to take up a new appointment as head of the division of experimental biology and virology *He will also be responsible* (under the director, Dr G F Marrian) for the general administration of the Mill Hill laboratories

Dr A R Currie, at present assistant pathologist at the Royal Infirmary, *Glasgow*, has been appointed head of the division of pathology, and will take up *his duties on* Oct 1, 1959 The Fund is meanwhile giving financial support to the cancer research he is doing in the pathology department of the University of Glasgow

International Federation of Medical Electronics

At a meeting held in Paris in June, at the invitation of Dr Vladimir K Zworykin, of the Medical Electronics Center of the Rockefeller Institute, with the cooperation of UNESCO and a number of scientific societies, 76 representatives from eleven countries unanimously agreed

To set up an international federation of medical electronic organisations open to societies and individuals from all countries of the world, to hold an international meeting in Paris in the spring of 1959, to compile an international bibliography on medical electronics

Interim officers elected by the group include Dr V K Zworykin, president, Dr C N Smyth, vice-president and chairman of publications committee, and Mr B Shackel, treasurer

Royal Institute of Public Health and Hygiene

On Monday, Oct 13, at 5 P M, at the Institute, 28, Portland *Place*, London, W 1, Dr B G B Lucas will give the Bengue lecture His subject is to be artificial aids in the control of the circulation

Charterhouse Rheumatism Clinic

On Friday, Oct 10, at 5 30 P M, at 54, Weymouth Street, London, W 1, Prof *S* de Sèze, of the Centre de Rhumatologie Viggo-Petersen, Paris, will give the Gilbert Scott lecture He is to speak on postmenopausal trophostatic *pain*

Scientific Film Association

A medical section of this association is being formed and the inaugural meeting will be held on Monday, Sept 8, at 6 P M *at the film theatre*, room 103, Shell-Mex House, Strand, London, W C 2, when *Stress and the Adaptation Syndrome* (U S A 1957) and *Jugular Venous Pulse* (Great Britain, 1958) will be shown Further information may be had from the secretary at the association's new address, 3, Belgrave Square, London, S W 1

On Thursday, Oct 2, at 3 P M, at the Royal College of Physicians of London, Pall Mall East, S W 1, Sir Hartley Shawcross will give the inaugural address to Charing Cross Hospital Medical School

The National Association for the Prevention of Tuberculosis and Diseases of the Chest and Heart, with the chest clinic service of Glasgow, is holding a symposium on the catarrhal child, on Wednesday, Oct 1, at 3 30 P M, at the Royal Faculty of Physicians and Surgeons, 242, St Vincent Street, Glasgow, C 2 Prof Stanley Graham will be in the chair and the speakers will include Dr Catriona Sinclair, Dr A W Lees, Prof J W Howie, Dr William Blair, Dr R H Dobbs, Prof Wilfrid Gaisford, and Dr R J Cuthbert Tickets (10*s*) may be had from the N A P T Scottish Branch, 65, Castle Street, Edinburgh, 2

The *British* Commonwealth and Empire Nurses War Memorial Fund has awarded twelve scholarships for 1958–59 Nine go to nurses and midwives in the United Kingdom and three to nurses from the Commonwealth

The Scottish group of the Nutrition Society is holding a symposium in Edinburgh on Saturday, Sept 27, on nutritional hazards caused by radioactive contamination of foods Further particulars may be had from Dr J Davidson, Rowett Research Institute, Bucksburn, *Aberdeenshire*

Dr J W Galloway is to *succeed* Dr T H J Douglas as chief dental officer of the Department of Health for Scotland at the end of the year

Dr J *M* Walshe is spending two months in Argentina and Chile under the auspices of the British Council He is to visit the Universities of Buenos Aires, Cordoba, Rosario, and Chile

The Danish Surgical Society has become a member institution of the International Federation of Surgical Colleges

The second Doctors' Hobbies Exhibition *is to* be held at B M A House, Tavistock Square, London, W C 1, from Nov 10 to 14 Entry forms may be had from the public relations officer, Benger Laboratories Ltd, Holmes Chapel, Cheshire Entries close on Sept 12

The editorial and publishing offices of the *Pharmaceutical Journal* have been moved to 17, Bloomsbury Square, London, W C 1

A second edition of Notes on the Diagnosis of *Occupational* Diseases prescribed under the National Insurance (*Industrial* Injuries) Act has been published by H M Stationery Office (3*s*) The *notes* were compiled in 1950 *for the* guidance of doctors examining, for the Ministry of Pensions and National Insurance, claimants to benefit Since then three new diseases (tuberculosis, primary neoplasm of the epithelial lining of the urinary *bladder, renal pelvis,* or *ureter, and* cadmium poisoning) have been added to the schedule of prescribed diseases, and the schedule has been revised and reorganised on the lines of the recommendations made by the Industrial *Injuries* Advisory Council

---

CORRIGENDUM *Eponyms in Medicine* —In this annotation (Aug 30, p 452) we described Thomsen's disease as amyotonia congenita, whereas it is really myotonia congenita—a much *different* disorder Our error illustrates with disconcerting immediacy the need *for the* advice, which we offered in the same annotation, that when eponyms are used "contributors and editors must strive to ensure that they are placed in a correct context and accurately rendered"

The Lancet · Saturday 13 September 1958

MALIGNANT DISEASE OF THE URINARY TRACT *

Sir Eric Riches
M C, M S Lond., F R C S
SURGEON AND UROLOGIST, THE MIDDLESEX HOSPITAL, LONDON, W 1

1773, the year of the foundation of the Medical Society of London by Lettsom and of the Boston Tea-party, also saw the birth in Frankfurt of a certain Bozzini He was the inventor of the first cystoscope, a primitive instrument in which light from a candle was reflected down a long tube passed into the bladder Two years after the delivery of the first Lettsomian lecture Desormeaux added a lens and a gas lamp, and in 1876 Nitze produced the prototype of the modern cystoscope The discovery of X rays by Rontgen in 1895 was another milestone in urological diagnosis, and it was in the same year that Rehn reported an increased incidence of bladder tumours among aniline dye workers

THE BLADDER

I have reviewed the notes of 565 of my patients with carcinoma of the bladder No cases have been included unless malignancy was verified either histologically at the time or by subsequent events The sex-incidence was 417 males to 148 females Their ages ranged from twenty-three to ninety, with an average of sixty-two years

Pathology

Types

Carcinoma of the bladder is seen in two main forms which differ so much in appearance and behaviour as to suggest two different diseases

On the one hand there is the *papillary tumour* it resembles the benign papilloma, save that its villi tend to be more stunted, its pedicle is wider, and its surface is often flecked with phosphates These tumours may be single, but they are often multiple or confluent, they should be regarded as a disease affecting the mucosa of the whole bladder They can spread in a wound by spill and implantation when the bladder is opened, and such implants often lose their gross papillary form and become solid. In the course of time they can infiltrate the muscle layer and penetrate the perivesical tissues Lymphatic or vascular metastases may also be found, but spread is mainly along the mucous or submucous lining and by bulky proliferation into the cavity of the bladder itself

On the other hand there is the *solid tumour*, nodular in cystoscopic appearance, usually single and localised. Its tendency is to infiltrate the underlying muscle early, to invade lymphatics and blood-vessels, and in time to become fixed to the pelvic wall It has a higher intrinsic malignancy than the papillary tumour and it must be caught early if it is to be cured.

Stage

The extent of penetration into or through the bladder wall determines the stage of the disease, it is important in assessing operability and prognosis It can only be told with certainty after the whole thickness of the wall, or the whole bladder, has been removed, but a fairly accurate clinical assessment can be made on bimanual examination under full anæsthetic relaxation I have grouped all my cases in which staging was possible into groups A, B, and C corresponding with the mucosal, muscular, and perivesical stages of infiltration

Grade

Another pathological feature which influences the behaviour of bladder cancer is the histological degree of malignancy, known as the grade of the tumour For many years we have followed the system, described by Dukes and Masina (1949) of recognising three such grades—low, medium, and high. Though there is a correlation between grade and stage, the grade of malignancy is more important in the papillary tumours, whilst the stage of penetration gives most information in the solid growths

Rare Forms

Pure squamous-cell growths occur, apart from tumours which show areas of squamous metaplasia and primary columnar-cell adenocarcinomas may arise from the urachus or from the mucous glands of the base There are 3 cases of sarcoma in this series

Diagnosis

Hæmaturia is the outstanding clinical feature of cancer of the bladder in this series it was present in 97% of over 500 patients In secondary growths, due to extension from other viscera, the proportion of patients with hæmaturia was 75% Occasionally the first symptoms are those of cystitis with frequency and pain, but the urine is often sterile

Cystoscopy with a small examination cystoscope under a local anæsthetic usually suffices to establish the diagnosis, but the investigation should always be repeated under a general anæsthetic with an instrument with a good irrigating channel, a clear wide-field telescope, and plenty of time

The excretion pyelogram will show whether the upper urinary tract is normal, a dilated ureter above a growth usually indicates infiltration. A "bite" deformity in the cystogram is suggestive of a solid growth, whilst a papillary tumour can be recognised by the irregular distribution of the medium between the fronds The size of the tumour can be assessed with reasonable accuracy from the X-ray pictures

At the time of cystoscopy a piece of the growth should be removed for biopsy, and the empty bladder should always be examined bimanually under full relaxation A tumour of average size is palpable, a solid tumour is firm and may be mobile or fixed, a papillary tumour is softer and more often mobile within the bladder A firm easily palpable tumour indicates infiltration of the bladder wall The urine should be examined bacteriologically

Treatment

Guiding Principles

New types of treatment continue to appear and the clinician must be constantly ready to change his method of attack I believe that the greatest hope at present lies in the combination of surgery and radiotherapy The collaboration between the two must be a true partnership for the benefit of the patient, and in no sense must it be competitive Perhaps when our concepts of ætiology are further clarified our treatment will become partly biochemical.

---

* Based on the first of three Lettsomian lectures for 1958 delivered before the Medical Society of London. The full text will later appear in the *Transactions* of the society

If the disease is one which affects the whole bladder, then treatment should in theory be by total cystectomy or total irradiation As it is the papillary growth which has this tendency most, one might make a case for total cystectomy or irradiation for all papillary tumours Yet experience shows that if such tumours are not extensive when first seen they can be kept in control by local treatment, and some do not recur 70% five-year survival can be obtained by cystodiathermy alone in papillary carcinoma of low malignancy, but the high recurrence-rate shows the widespread liability to the disease

Solid growths, on the other hand, more often appear as single lesions If seen early and in an accessible position they can be removed by partial cystectomy or segmental resection with good prospect of success Too often, however, they have reached the stage of perivesical or distant spread, or they are of high malignancy. In such cases control is unlikely, whatever the method of treatment, though considerable palliation can be given by supervoltage X-ray therapy

Radiosensitivity is directly proportional to the degree of malignancy, and the finding of a high degree in a papillary tumour should be an indication to introduce some form of irradiation into the treatment Whilst conventional (200 kV) therapy has a limited value, the possibilities of the supervoltage machines are much greater (Busby 1957, Swinney 1957, Cavazzana 1957) I am fortunate in having the collaboration of Professor Windeyer with the large machines at Mount Vernon Hospital Our two-year experience with them is too recent for the presentation of results in detail, but we can report a satisfactory regression in papillary tumours and better palliation in the infiltrating growths than by any other method

Though supervoltage therapy has the great advantage of producing little general reaction and only slight skin changes, one untoward result of any form of effective irradiation is the production of telangiectases in the bladder These small vessels have a tendency to bleed, arousing a suspicion of recurrence Light cystodiathermy may check the bleeding, but too deep coagulation may make it worse Another occasional unpleasant sequel is radionecrosis and a contracted bladder, it is more common if the treatment has been given too quickly I have seen it in 2 cases treated by intracavitary irradiation with a solid bead of cobalt-60, both of which needed cystectomy, and in 2 whose growths were very effectively treated by Mr Wallace with intracavitary liquid isotopes

Diversion of Urine

Urinary diversion is necessary before total cystectomy and must be seriously considered before radical X-ray treatment Ureterocolostomy has fallen somewhat out of favour owing to the risk of acidosis, but ureteroileostomy, which is free from this risk, carries the need to wear a receptacle for the urine Though most patients manage the receptacle well, I feel that there is still a place for ureterosigmoidostomy with proper electrolyte control

I have also done palliative urinary diversion in 50 cases, and palliative cystectomy, where the growth was already beyond the bladder, in another 34 9 further patients were deemed untreatable by surgery or by irradiation when first seen Of these 93 patients, for whom there was no real hope of cure, 16 lived for more than a year, 1 lived and worked for seven years after cystectomy, before dying from metastases, and 1 remarkable man is still alive and working more than eight years after ureterocolostomy followed by excision of the dome of the bladder and the insertion of radium needles into an anaplastic carcinoma that was adherent to the pubes Palliative surgery in th disease will not give good statistics but it will prolong life in comfort

Choice of Treatment

For the potentially controllable case there is a w choice of treatment, but we must realise that tables results compare not so much the merits of differe methods as the different types of growth encountere Good results are an indication that the right type treatment was chosen for that particular growth b results show that either the wrong treatment was chose or that the tumour had a very high intrinsic malignanc or that it was too far advanced when first seen Th choice depends on the general condition and renal fun tion as well as on the type, size, situation, multiplicity, a extent of the tumour, and on the presence of muco changes beyond it

PAPILLARY TUMOURS

Cystodiathermy

For localised, pedunculated, papillary, differentiat growths of small or moderate size my preference is f coagulation diathermy with removal of any residual stun by the resectoscope or biopsy forceps

The usual small bladder electrode is insufficient, except f small tumours, and I have found that a modification of Kidd cystoscope increases the range of the operation enormousl The instrument ends in a big ball electrode it has a wide fie of vision, and, of greatest importance, the same large irrigati fitting as the standard cystoscope Tumours of considerab size can be destroyed at one sitting, and it is the first treatme which matters most Repeated nibbles at the surface with small electrode are unsatisfactory and may be harmful

Endoscopic treatment was used in 153 cases, and th five-year survival-rate is shown in table I

TABLE I—FIVE-YEAR SURVIVAL-RATE AFTER TREATMENT BY CYSTODIATHERMY

—	No	5-year survival
Low grade or stage High grade or stage	112 (73%) 41 (27%)	43/60 (72%) 8/25 (32%)
Total	153	51/85 (60%)

Operative mortality, 1/153 (0 6%) *10-year survival, 13/40 (33%)*

Survival for any given period does not tell the whol story, for 75% of these patients needed more than on session of treatment The so-called recurrence-rate ofte represents residual tumours it appears to be lessenin since the adoption of the big-ball cystoscope during th past two years Distant metastasis is uncommon from low-grade tumour, but it can occur at any time

Open Diathermy Excision

In patients with papillary tumours too large for cysto diathermy, or who are unfit for total cystectomy, th bladder can be opened and the growths excised down t the muscle The method was also used for a time, wrongl as we now think, for inoperable high-grade or infiltratin tumours in them it affords poor palliation In any cas spill of urine or tumour is a danger that must be avoided In the low-grade but extensive cases the survival i remarkably good so long as regular follow-up cystoscopic and diathermy treatment are carried out

Of the 28 patients treated in this way 3 subsequently need total cystectomy, 1 of whom is alive ten years later Ther have been 7 five-year survivors and 3 ten-year survivors There was 1 operative death

Excision of Mucosa

As a variant of open diathermy excision I have on 2 occasions excised the mucosa of the bladder

A woman of fifty-eight had extensive papillomatosis I removed the whole area down to muscle with the diathermy needle but left a little apparently normal mucosa on the trigone and around the ureteric orifices In over two years she has had two small recurrences, but the mucosa has regenerated completely Histologically the tumours were papillomata

The other patient, a man of sixty-one, had cystodiathermy in 1952 and 1953 for a low-grade non-infiltrating papillary carcinoma with some squamous metaplasia He defaulted until 1957 when he returned with a bladder full of papillary growth In October, 1957, I excised the entire mucous membrane of the bladder A month later the bladder had a more normal appearance on excretion urography, but he had hourly frequency A cystogram at two months, whilst showing a smooth bladder outline, also showed a bilateral ureteric reflux Three months after operation cystoscopy showed for the most part a pale trabeculated bladder with no apparent mucosa There were some red areas where mucosa appeared to have regenerated, and biopsy confirmed this There was no recurrence of growth but the capacity was only 3 oz The bladder was distended by a balloon to $7^1/_2$ oz This caused considerable bleeding which lasted for twenty-four hours but resulted in some improvement of his frequency It is still possible that he will have to undergo urinary diversion

TABLE II—FIVE-YEAR SURVIVAL-RATE AFTER TREATMENT WITH RADON SEEDS

Grade	No	5-year survival
Papillary differentiated	49	26/37 (*70%*)
Poorly differentiated	33	12/24 (*50%*)
Anaplastic	18	5/12 (*42%*)
Total	100	43/73 (*59%*)

Operative mortality 4/100 (*4%*)

I cannot recommend this operation yet but recent American work on dogs had shown that, after mucosal denudation, bladder contracture and ureteric reflux do not occur if a cuff of mucosa is left around the ureteric orifices (Sanders et al 1958) My 2 cases confirm this observation

Intravesical Implantation of Radioactive Material

When a papillary tumour is of high-grade malignancy, its chances of recurrence after cystodiathermy are high, and a better result can be expected from an implant I have used radon seeds since 1946, but in 1956 I changed to gold grains irradiated in the atomic pile The effect of the two appears to be the same Irradiated tantalum wire can also be used and, since it has a half-life of 112 days, some can be kept in stock I believe, however, that it is more often followed by radionecrosis than the other two substances Insertion is preferably done by open operation the implant is permanent and the bladder can be closed I have used radon seeds in exactly 100 cases (table II).

The local result of radon implantation in an anaplastic growth may be excellent, but it may not prevent distant metastases in the liver and aortic glands

On comparing five-year survivals there is nothing to choose between cystodiathermy and radon implantation in respect of low-grade tumours In high-grade tumours radon shows an appreciable gain Treatment for recurrences was necessary in 75% of the diathermy cases and only in 42% of the implants

Cystectomy

Although partial cystectomy is sometimes suitable for large papillary tumours, there are often mucosal changes, or even small tumours, remote from the main growth, and these make total ablation the better procedure For extensive or multiple papillary tumours total cystectomy offers the best prospect of complete control It carries the added risk of deviation of the urine, and it should not be left to be undertaken as a last resort, as so often happens The operation has its best results in tumours of low malignancy (table III) The newer forms of radiotherapy have got to prove themselves before it can be abandoned

TABLE III—FIVE-YEAR SURVIVAL-RATE AFTER TOTAL CYSTECTOMY

Group	No	5-year survival
A (mucosal)	37	11/28 (*39%*)
B (muscular)	39	3/31 (*10%*)
C (perivesical)	34	1/24 (*4%*)
Total	110	15/83 (*18%*)

Operative mortality, 14/110 (*12 7%*)

The statistical results of total cystectomy appear poor, but the operation is generally used for the most extensive cases of papillary tumour Of the 11 patients in group A who passed the five-year mark 10 are still living and 1 died from heart-disease after eleven years Muscular penetration worsens the prognosis considerably, and when there is perivesical extension the operation should be regarded as palliative

SOLID TUMOURS

Localised solid nodular tumours, the "bun" carcinomas—if they are not too large, if they do not involve the bladder base, and if there are no mucosal changes elsewhere—are best treated either by partial cystectomy or by extravesical radium implantations

Partial Cystectomy

The excision must be generous and include the whole thickness of the bladder with a patch of peritoneum Mucosal changes beyond the tumour determine the need for total cystectomy In my experience this type of bald tumour is getting less common than the mixed solid and papillary type of high-grade malignancy with infiltration (table IV)

TABLE IV—FIVE-YEAR SURVIVAL-RATE AFTER PARTIAL CYSTECTOMY

Group	No	Survival	
		10 years	5 years
A (mucosal)	17	3/9 (*33%*)	7/12 (*58%*)
B (muscular)	56	9/32 (*28%*)	16/44 (*36%*)
C (perivesical)	15	0/6 (*0*)	0/6 (*0*)
Total	88	12/47 (*26%*)	23/62 (*37%*)

1 sarcoma survived $6^1/_2$ years Operative mortality 6/89 (*6 7%*)

Chances of survival at ten years and at five years diminished with increasing depth of penetration of the bladder wall only 2 patients with perivesical extension lived for more than one year Those with muscle penetration predominated, and survival of 28% at ten years was surprisingly good The most favourable site is the dome There were 4 cases of urachal tumour in which the umbilicus and urachus were excised en bloc with the bladder tumour 1 is still living over twelve years later For tumours near the ureteric orifice there should be no hesitation in reimplanting the ureter This was done in 14 patients and only 2 kidneys were lost The longest survivor, now eighty years old, was operated upon more than twenty-one years ago and had the ureter reimplanted At no period, however, can one speak of "cure" New tumours, the so-called recurrences, may come at any time Mostly they are of the same grade as the original, but a different tumour may appear

Radium Implantation

Because of the severe and prolonged cystitis which affects the bladder if it cannot be immediately closed, the implantation of radium needles from the inside is out of favour Higham (1955), however, has devised an ingenious method of application on a rubber mould which does allow closure In accessible solid tumours it is possible to implant radium from outside without opening the bladder When high-grade malignancy indicates the need for irradiation this is an alternative to partial cystectomy I have treated 15 patients in this way, all but one with high-grade solid tumours The longest survivor is still living after nearly five years Even if not curative the local irradiation may make the tumour operable

Intracavitary Irradiation

Much—perhaps too much—was hoped from a method which promised uniform irradiation of the whole bladder from a central source The results of treatment are shown in table v Cobalt 60 was used in 11 cases and radium in 2

TABLE V—RESULTS OF TREATMENT WITH INTRACAVITARY IRRADIATION

Lived 3–5 years	4
Lived 1–2 years	6
Lived less than 1 year	2
Operative mortality	1

The only real successes were in non-infiltrating papillary tumours, and the method has now been abandoned

MISCELLANEOUS TUMOURS

In the series there were 11 cases of growth in a diverticulum Most of these are of high grade and infiltrate quickly through the thin wall of the sac, becoming fixed In 32 cases the bladder was invaded from some other viscus in 13 the primary growth was in the uterus or ovary, in 4 in the large intestine, and in 15 in the renal pelvis or urethra Sometimes wide excision of two invaded viscera is possible, and occasionally a pelvic clearance is indicated The cure of a vesicovaginal fistula is always worth while

3 cases of sarcoma were treated by combined irradiation and surgery, 1 lived for eight years, 1 for six and a half, and 1 is living at nearly four years

Conclusions

I have tried to indicate that cancer of the bladder exists in two principal forms The papillary differentiated growth can be relatively benign and readily controlled the solid anaplastic tumour is always very malignant

Duplicity in the more worldly sense is evident from the insidious clinical onset and the late recurrences of the disease The prognosis may appear to depend more on the type of growth than on the treatment, but the disease does at least run true to form It will give early warning of its potential malignancy if the patient is fully examined and carefully assessed

THE MEASUREMENT OF THE PREVALENCE OF ISCHÆMIC HEART-DISEASE

ARTHUR J THOMAS
M D, B Sc Wales, M R C P, D P H
CONSULTANT PHYSICIAN, UNITED CARDIFF HOSPITALS

A L COCHRANE
M B Cantab, D P H

I T T HIGGINS
M D Lond, M R.C.P

MEMBERS OF SCIENTIFIC STAFF, PNEUMOCONIOSIS RESEARCH UNIT OF THE MEDICAL RESEARCH COUNCIL, LLANDOUGH HOSPITAL, PENARTH, GLAM

EVIDENCE from death-rates, autopsy studies, and hospital and clinicians' records suggests that the amount of ischæmic heart-disease differs in different communities (Keys and White 1956) Such evidence has been invaluable in suggesting hypotheses about the ætiology of the disease which require testing quantitatively in more representative samples of the population

Of the two epidemiological indices of morbidity, one would prefer to know the attack-rate (inception-rate or incidence) or rate of appearance of ischæmic heart-disease in the community This, however, is difficult to measure, because it needs a detailed follow-up of a large, fully examined, and well-defined group The alternative index, prevalence (i e, the proportion with ischæmic heart-disease in the community at a given time), is an essential preliminary measurement for establishing attack-rates, is more readily determined, and is the one considered in this paper

In the United States the measurement of both these indices is in progress, and preliminary results have been published (Dawber et al 1957, Doyle et al 1957, Chapman et al 1957, Epstein et al 1957, Drake et al 1957) These admirable studies are open to possible criticism, however, on the ground that, although attention is always paid to diagnostic criteria, reproducibility of these criteria has not been investigated, and consequently it is impossible for others, obtaining different values for the prevalence of ischæmic heart-disease in other populations, to know whether they are dealing with an artefact or a true epidemiological difference

Both Doyle et al (1957) and Chapman et al (1957) studied groups of Civil Service employees, the former in New York State, the latter in Los Angeles, while Epstein et al (1957) investigated New York clothing workers Such working populations are not necessarily representative of the whole community from which they were drawn, since, apart from occupational self-selection and social class, those who may have retired because of ill health are automatically excluded Lastly, bias could have been introduced by the rather high refusal rates in Framingham (31%) (Dawber et al 1957), and Los Angeles (25%) (Chapman et al 1957)

Hence there seems to be a real need for techniques for measuring ischæmic heart-disease in unselected populations and ensuring comparability of the medical indices used We discuss these two problems, using material from a survey of representative occupational samples of two communities

Prevalence is essentially a ratio—in the present context the ratio of those suffering from ischæmic heart-disease to the population at risk Difficulties and errors may arise, therefore, not only in identifying the cases of ischæmic heart-disease but also in defining, sampling, and measuring the community from which they are drawn The latter problem is usually neglected—partly because its importance is not appreciated, but partly perhaps because people are secretly rather frightened of it

Measurement of the Population at Risk

Our method has been to define a geographical area, enumerate the inhabitants by a private census, and then carry out a chest X-ray survey (Cochrane et al 1955, Cochrane, Miall, and Clarke 1956) The information thus obtained is transferred to punch cards from which samples can readily be drawn

The first of the two surveys of ischæmic heart-disease was made in 1954 on a random sample of miners and ex-miners living in the Rhondda Fach, a mining valley in South Wales (Thomas et al 1956) The second survey was designed to achieve an occupational contrast An agricultural area, the Vale of Glamorgan, which is 15 miles from the Rhondda Fach, was chosen, and in 1956 a random sample of men aged 55–64 who lived in this area and had never been miners was investigated

Those who appeared in the sample were visited by members of the epidemiological team at the Pneumoconiosis Research Unit and persuaded to cooperate The vast majority were transported either to the unit or to a centre in Cowbridge, in the Vale of Glamorgan, where the examination took place The " response " rate and other details are shown in table I

The first survey was a pilot investigation in which the sample was limited to 55 men In retrospect we consider this too few, and in the second survey we increased the sample to 100 Certain problems are introduced by the measurements being made some time after the nominal census The sample will inevitably include some people who have died or left the area in the interval We have not attempted to substitute others for these, but we have carefully investigated the cause of death in the former and have excluded the latter from the population at risk

TABLE I—RESPONSE-RATE IN THE TWO SURVEYS

Area	No in sample	No left area	No dead	No of refusals	Response-rate of those still in area and still alive
Rhondda Fach	55	2	2	4	47 (*92%*)
Vale of Glamorgan	100	4	1	10	85 (*90%*)

The other source of error relates to the proportion of the sample responding to our persuasion The percentages shown in table I are high They could, of course, be higher, but at present we know of no technique for reducing the refusal-rate below 5–10% Possibly others will discover one

Measurement of the Number with Ischæmic Heart-disease

The diagnosis of ischæmic heart-disease is usually based on clinical, radiological, and electrocardiographic evidence Analysis of the results of the first survey suggested strongly that the electrocardiogram was by far the most important factor in making the diagnosis, that the clinical examination was sometimes valuable, and that the posteroanterior chest X-ray was relatively unimportant Further investigation shows that there is considerable variation in the diagnosis Comparison of the conclusions of several cardiologists, based on clinical and electrocardiographic examination of all members of the sample, would have been desirable, but this proved impossible and we have had to compromise In both surveys we have arranged for the same clinician to make a diagnosis on the clinical and electrocardiographic evidence In addition, all the electrocardiograms have been interpreted by two other cardiologists

Our two main problems have been (1) the difficulties of obtaining satisfactory electrocardiograms and (2) the difficulties associated with different interpretations of the same tracing

Technically perfect electrocardiograms are harder to obtain under survey conditions than in hospital—partly because time is limited and partly because it is difficult or impossible to recall a member of the sample in order to repeat the investigation In neither of our surveys were the electrocardiograms perfect but in the second survey they were much better than in the first, and in a more recent survey they were nearly up to the best hospital standard There is, in addition, the question of which leads and how many should be taken to satisfy different cardiologists In future we intend to take the 12 standard limb and chest leads Our experience also suggests that a direct-writing electrocardiograph has considerable advantages over one recording photographically Unsatisfactory tracings can be immediately repeated before the subject departs, and additional leads can be added at the discretion of the cardiologist making the clinical examination

The differences of interpretation presented a more serious problem Photographic prints of the electrocardiograms from the two surveys (concealing the origin of the tracings) were mixed at random and read independently by each of the three cardiologists, who were asked to record their observations on a standard form The cardiologists* reported on the tracings as they would have done in ordinary clinical practice They *held no prior discussion on the criteria for diagnosing* ischæmic heart-disease The diagnostic criteria used by the third observer (A J T) were those detailed previously (*Thomas et al 1956*) and we expected that those used by the other two readers would be broadly similar The results are shown in table II It is clear that there were considerable differences of interpretation The commonest cause of disagreement was the borderline tracing, next was the difficulty of differentiating cardiac hypertrophy, with or without associated strain, from ischæmia, and lastly, some differences may have been due to unsatisfactory tracings and to the wording of the form (but exclusion of the unsatisfactory electrocardiograms did not produce any significant improvement) In future surveys we shall use a more precise form Observer differences might be further reduced by preliminary discussion of precisely what abnormalities are to be accepted for diagnosis

In view of the observer differences we have adopted two indices for the analysis of the results When the diagnosis of ischæmic heart-disease has been reached on complete clinical, radiological, and electrocardiographic assessment, we speak of the " clinical " index, when we have used those electrocardiograms which all three observers regarded as showing ischæmic heart-disease we speak of the " electrocardiographic " index The advantage of the first index is the use made of the valuable information supplied by the clinical examination Its main disadvantage is the difficulty, in comparative studies, of preventing possible bias through the clinician knowing the area from which the subject comes The advantage of the " electrocardiographic " index is the ease with which such bias can be avoided

Results

Prevalence in the Two Areas

If we restrict ourselves to the two indices we can compare the prevalence of ischæmic heart-disease in the two

TABLE II—PREVALENCE OF ISCHÆMIC HEART-DISEASE DIAGNOSED CLINICALLY AND/OR ELECTROCARDIOGRAPHICALLY IN THE TWO COMMUNITIES BY VARIOUS READERS

—	Vale of Glamorgan (85 cases)	Rhondda Fach (47 cases)
Diagnosed clinically (clinical index)	19 (*22%*)	18 (*38%*)
Diagnosed electrocardiographically		
By all 3 readers (electrocardiographic index)	12 (*14%*)	10 (*21%*)
By 2 of the 3 readers	6 (*7%*)	2 (*4%*)
By 1 of the 3 readers	16 (*19%*)	10 (*21%*)
Total (by any of the 3 readers)	34 (*40%*)	22 (*47%*)
Corrected * clinical index	22 (*25%*)	18 (*38%*)
Corrected * electrocardiographic index	15 (*17%*)	10 (*21%*)

* When the 3 additional Vale cases are included

populations, as shown in table II This, however, is not entirely satisfactory

Among those who refused examination there were 2 in the Vale of Glamorgan who had been diagnosed in hospital as suffering from ischæmic heart-disease and whose electrocardiograms were reviewed by one of us (A J T) It was impossible to include their electrocardiograms in the series sent to the three readers, but we think that they should be added to both indices The case of the man who appeared in the sample but died of ischæmic heart-disease before the survey presents a somewhat different problem, but we believe that he too should be included in both indices The effect of these additions is shown in table II The difference between the two areas is much reduced

We conclude that we have not been able to prove the existence of a significant difference in prevalence of ischæmic heart-disease between the two areas The possibility of its existence has not, of course, been excluded

Characteristics of Populations in Relation to the Disease

Another advantage of this type of prevalence study is the opportunity it gives of comparing those with ischæmic heart-disease with those of the same age and sex living in the same area without ischæmic heart-disease Such a control group is clearly preferable to the more usual one, drawn from hospital patients

Personal and anthropometric characteristics (table III)—There was little difference in either area in the average age of the ischæmic and control groups Both indices showed a considerable difference in average weight between the two groups, and smaller differences in standing and sitting height, and in nearly all cases the "electrocardiographic" index, which probably indicates the more severe cases, gives a greater difference than the "clinical" index Arm girth and arm skinfold measurements were available only for the Vale population The results suggest that the higher average weight of those with ischæmic heart-disease is more likely due to muscle than to fat

TABLE III—ANTHROPOMETRIC CHARACTERISTICS

—		Vale of Glamorgan		Rhondda Fach	
		Ischæmic heart-disease	Others	Ischæmic heart-disease	Others

Physiological and biochemical factors (table IV)—The raised blood-pressure and the indirect maximum voluntary ventilation (M V V) in those with ischæmic heart-disease have been previously described (Cotes et al 1956) One point of interest is the decreased difference in systolic blood-pressure when the "electrocardiographic" rather than the "clinical" index is used This was due to the difficulty of diagnosing ischæmic heart-disease in the presence of left ventricular preponderance, which led to disagreement between observers Our findings about height are also of interest in relation to the higher M V V in the group with ischæmic heart-disease The increased height is found both for total height and stem height, and probably accounts for some of the difference in *M V V* The data about cholesterol are being published elsewhere (Morris, to be published) The difference (*11 ± 14 6 mg per 100 ml*) between those with and those without ischæmic heart-disease is small and statistically insignificant

TABLE IV—PHYSIOLOGICAL AND BIOCHEMICAL CHARACTERISTICS

5 P=0 01

Family data—The information in table V was obtained from the members of the samples at the time of the examination in the case of the Vale of Glamorgan, and two years later in the case of the Rhondda Family size appears not to be correlated with ischæmic heart-disease, for the results differ in direction in the two surveys The survival rate of the fathers of those with ischæmic heart-disease seems unexceptional they appear to do rather better than the fathers of the controls Conversely, the mothers of the ischæmic heart-disease group do rather worse than the mothers of the controls, but the differences are not significant The most striking results come from the brothers and sisters In every comparative pair there is a higher mortality among the siblings of the group with ischæmic heart-disease The pairs where the differences are statistically significant are indicated in the table

The causes of death of brothers and sisters have been investigated in both areas, but with such small numbers it is very hard to draw any conclusions as to the causes of the excess mortality

Other factors—In the paper reporting the survey of ischæmic heart-disease in the Rhondda Fach an attempt was made to test the hypothesis advanced by Morris et al (1953) that hard manual work reduces the risk of developing the disease The average number of years at the coal face in the two groups was compared, on the assumption

TABLE V—FAMILY DATA

that coal-face work is on the average harder than other work in a mine, but no significant difference was found The material has now been reanalysed using the "electrocardiographic" index Those diagnosed electrocardiographically as having ischæmic heart-disease had worked for 5 7 years on the coal face compared with 16 9 years for the controls The difference of 11 2 years is statistically significant (0 005>P>0 001) This, in general, supports Morris's hypothesis, but the results could be due to men with heart-disease leaving the coal face early, or to some other type of occupational selection.

We have also some information about mean chest diameter This was measured on a high proportion of the miners and ex-miners in the Rhondda during the first Rhondda Fach survey Using the clinical index, the mean chest diameters of those with and without ischæmic heart-disease was 27 8 cm and 26 9 cm, and using the electrocardiographic index the figures were 28 1 cm and 26 5 cm

The material has also been analysed as regards smoking habits and social status (using the Registrar General's classification), but no significant correlations have emerged.

Discussion

Measurement of Prevalence

The essential difficulty in comparing the prevalence of ischæmic heart-disease in different areas is to avoid bias due to preconceived hypotheses The electrocardiogram is the only suitable means of ensuring that such bias is eliminated Tracings from different areas can be mixed and read by observers who are not told where they come from In such circumstances the precise level of diagnosis of ischæmic heart-disease is relatively unimportant since the criteria adopted can be assumed to be the same for all the tracings, comparisons between areas or between occupations will be valid Hence we believe that our comparisons in the present paper are justified On the other hand the wide variation in interpretation of electrocardiograms makes us sceptical of our absolute values for the prevalence of ischæmic heart-disease, and shows that much more work must be done before the findings of workers in different centres can be justifiably compared Though the differences may disappear under the impact of the discussion caused by their measurement more basic research is likely to be needed. This will include the correlation of clinical and electrocardiographic findings with post-mortem findings on unselected groups, and the follow-up of large unselected populations to determine the relation between electrocardiographic abnormalities and expectation of life

Ætiology of Ischaemic Heart-disease

A widely entertained hypothesis relates ischæmic heart-disease to the fat content of the diet and to the blood-cholesterol (Keys 1955, Bronte Stewart et al 1955) There is evidence from many countries that people who live on diets low in animal fats tend to have a low mean serum-cholesterol level and little liability to ischæmic heart-disease (Keys and White 1956) While certain discrepancies in this hypothesis have been noted (Morris 1956, Yudkin 1957), the relevance of the blood-cholesterol to ischæmic heart-disease is supported by the observation at Framingham (Dawber et al 1957) that people with a high total blood-cholesterol were more liable to an episode of ischæmic heart-disease

In our investigation of men aged 55-64 the mean serum-cholesterol was insignificantly higher in those with ischæmic heart-disease than in the controls This is at variance with the findings of Gertler and White (1954) in young adult males Though racial differences between the groups studied—as demonstrated between Italians and Jews in the clothing workers' survey (Epstein et al 1957)—might account for this discrepancy, a more probable explanation is that over the age of 55 we are dealing with a survivor population those who had a high blood-cholesterol in their 30s and 40s had already died of ischæmic heart-disease. Alternatively, disordered lipid metabolism may be important mainly at younger ages Biorck et al (1957) concluded that, in people under 50 years old, the serum-cholesterol was higher in those with myocardial infarction than in normal controls, but over this age the difference was insignificant

The differences in blood-pressure and maximum voluntary ventilation (indirect) have been discussed previously (Thomas et al 1956, Cotes et al 1956) Since then, Epstein and his coworkers (Epstein et al 1957) have confirmed the raised blood-pressure in Italians with ischæmic heart-disease in New York, but not in Jews As we have also found a significant relation between ischæmic heart-disease and body-weight, and weight is related to blood-pressure (Master et al 1950), one must be cautious in drawing conclusions

Our anthropometric results are of greater interest Gertler and White (1954), who give a good summary of the literature, found that among young males those with coronary disease were significantly shorter and lighter The striking difference between their results and ours is possibly explained by their dealing with young males Alternatively, some bias may have been unintentionally introduced when selecting the 146 unmatched controls to compare with the 97 coronaries Epstein (Epstein et al 1957) apparently measured the heights of his population, but does not comment on any differences between those with and those without ischæmic heart-disease

As regards our family data, the situation is somewhat similar Here too the literature has been well summarised by Gertler and White (1954) They found that the parents of people with ischæmic heart-disease had a higher mortality than the parents of controls For this purpose their material was more suitable than ours, since the younger age-group made the measurement more sensitive They also found a higher mortality among the siblings of the controls (20%) than among siblings of the coronary group (15%), though the difference was not significant

We, on the other hand, found a significantly higher mortality among the siblings of those with ischæmic heart-disease Our data agree with theirs in showing no significant difference in the size of family in the two groups For this study our age distribution is more suitable

Faced with these divergent results we can only conclude that further work is required on similar populations, particular care being paid to the choice of controls

Summary

1 Comparison of the prevalence of ischæmic heart-disease in different places presents certain difficulties

2 The technique of random sampling from a population, accurately defined by private census, is illustrated by two surveys of men aged 55-64 The findings in a sample of 55 miners and ex-miners living in the Rhondda Fach are compared with the findings in a sample of 100 men who had never worked in dusty occupations, living in the Vale of Glamorgan

3 Three cardiologists independently read the electrocardiograms from each subject, and their findings varied considerably Hence, though the comparison of the two areas may be regarded as valid, the absolute prevalence values should be treated with reserve

4 Two indices of ischæmic heart-disease have been used

(1) The clinical index, based on clinical assessment, electrocardiography, and radiography, by one cardiologist

(2) The electrocardiographic index, based on agreement between three cardiologists that an electrocardiogram showed changes compatible with the diagnosis of ischæmic heart-disease

The prevalence in the two areas was

Clinical index Vale 25 0%, Rhondda Fach 38 3%
Electrocardiographic index Vale 17 0%, Rhondda Fach 21 3%

Though the mining group seemed to have a somewhat higher prevalence the difference was not statistically significant

5 Those diagnosed as having ischæmic heart-disease were both taller and heavier than the others

6 The siblings of the men with ischæmic heart-disease had a higher mortality than the siblings of the controls

7 No significant difference was found in the mean serum-cholesterol levels of the two groups

We wish to thank Dr J F Goodwin and Dr L G G Davies for reading the electrocardiograms, and for their invaluable suggestions, Dr B Bronte Stewart for reading the manuscript, Miss Barbara Snow, of University College, for statistical help, and our colleagues at the Pneumoconiosis Research Unit for their helpful advice and criticism, particularly Dr J C Gilson, director of the unit, Mr P D Oldham, statistician, and Dr T G Morris, who carried out the serum-cholesterol determinations

SENIOR HOUSE-OFFICERS TO THE DEPARTMENT OF NEUROLOGICAL SURGERY, NEWCASTLE GENERAL HOSPITAL

THE very severe head injury, complicated or uncomplicated by surface hæmorrhage, has always been the cause of grave concern to the neurological surgeon It has been noted that patients with cerebral lesions die in a characteristic way, and Jefferson (1944) wrote

> " It is the fate of all of us to watch patients with cerebral lesions dying from something characterised by tachycardia, and cardiac irregularity, from upsets of thermal regulation, from metabolic upsets which we have not yet found a means to study properly, from something that bears the hallmarks of a disease process as much as, say, pneumonia "

The distinguishing characteristics of the group of cases of head injury to be described here were a partial or complete decerebrate posture with tonic fits and a rapidly rising temperature Other signs of autonomic disturbance were usually present, but fell into no clear-cut pattern likely to be useful in routine diagnosis Kinnier Wilson (1920) described the association of this syndrome with lesions of the upper brain-stem and pointed out its resemblance to the effects of experimental transaction at the level of the superior colliculus in animals Other observers have confirmed and amplified Wilson's description

When the syndrome arises after head injury, *it is* probably the result either of intrinsic damage to the upper brain-stem, or of a mid-brain shift following a rise in supratentorial pressure When it arises as a secondary effect of raised pressure, it occurs late in the process of descent and indicates considerable damage amounting to partial or complete transection, which is not always reversible The signs arise from the paralysis of some structures and the action in isolation of others

Several types of herniation of supratentorial structures into the incisura have been described (Meyer 1920, Vincent et al 1936, Azambuja et al 1956), all of which eventually compress and distort the brain-stem or imperil its blood-supply The mechanics of these processes have been well reviewed by Johnson (1957), who points out that, while compression is often worst at the level of the incisura, structure must be distorted at all levels, and that, whatever the pattern of movement, when the pressure is supratentorial the whole brain-stem will shift down This downward shift may be sudden and catastrophic, but on the other hand it may be gradual, and in the latter case there may be little clinical evidence of the shift until a final and comparatively small further displacement leads to fatal compression

It is difficult clinically to identify accurately the causes of swelling of the brain in any given head injury, but morbid-anatomical and experimental evidence suggests that it is due to a combination of hæmorrhage, local œdema, and hyperæmia with the effects of hypoxia, carbon-dioxide retention, and " acceleration concussion "

Hæmorrhage is often found, and if massive may be the principal cause of displacement Of the cases to be described, in 27 out of 56 in the control series and in 15 out of 26 in the treated series, such hæmorrhage, subdural or extradural, was present Local œdema or its histological effects may be demonstrated in close proximity to lacerations of the brain and sometimes very near to the anterior part of the lateral ventricle This is likely to be only a contributory factor, as it occurs rarely if ever in a massive and generalised form (Greenfield 1938)

Hyperæmia of the brain is found at necropsy after concussion and has been so produced experimentally in cats White et al (1942) demonstrated hyperæmia of the brain in cats after inhalation of increased concentrations of carbon dioxide, and swelling of brain substance not due to hyperæmia in conditions of severe hypoxia Davies and McKinnon (1949) have shown the importance of the combined effect of hypoxia and hypercapnia in producing cerebral hyperæmia in man There is experimental evidence that generalised swelling of the brain which cannot be accounted for by hyperæmia, or correlated directly with water content, occurs after acceleration concussion. White et al (1943) recorded increases in brain volume of up to 5% in cats concussed by the method of Denny Brown and Ritchie Russell (1941)

When a brain-stem shift has occurred, other mechanisms come into play Compression or angulation of the brain-stem can obliterate the aqueduct, causing internal hydrocephalus Trapping of the transtentorial veins in the incisura will cause a rise of venous pressure and impede cerebral blood-flow

Johnson (1957) has drawn attention to the role of respiratory embarrassment in exacerbating downward displacement of the brain-stem by causing distension of intracranial veins Patients with severe head injuries commonly inhale mucus, vomit, and blood soon after injury, particularly if transferred to hospital in the supine position, and pooling of mucus in the pharynx is often observed Apart from these mechanical factors, mid-brain dysfunction itself leads to disorderly respiration In both cases venous pressure inside the skull must fluctuate considerably, and some observations made during the present series point to the importance of respiratory disorder as a precipitating cause of coning

3 patients in the series were admitted in a state of cerebral irritation and coma without focal signs, passed through an episode of mechanical respiratory obstruction, and then assumed a decerebrate posture with rising temperature Subdural hæmatomas were discovered at craniotomy in all 3 cases In these cases the appearances suggest that a large downward displacement existed with few clinical signs until a further slight descent provoked by the respiratory upset tipped the balance and produced a pressure cone

The role of respiratory insufficiency in the mortality of severe head injuries has been discussed by Maciver et al (1958), who outlined the regime which we have adopted, since Dec 13, 1956, in the treatment of such cases The most important features of the treatment are as follows

1 Correct posture to prevent seepage into the lungs and tracheobronchial tubes

2. Isolation of the lungs from the disorganised pharynx by early tracheotomy

3 Their further protection by continued aseptic tracheobronchial toilet.

4 The use of a lytic cocktail to coordinate the reticular mechanisms of the brain-stem, and control rigidity, restlessness, and hyperthermia

5 Avoidance of oral feeding during unconsciousness

6 Maintenance of physiological tensions of oxygen and CO_2 in the blood.

7 Maintenance of fluid and electrolyte balance and calorie intake.

8 Combating of infection by use of antibiotics

9 Relief or prevention of secondary cerebral œdema by use of intravenous triple plasma.

We describe here the details of treatment, the difficulties we have encountered, and the progress we have made Of 83 cases in the present series, 26 were treated by the regime described.

Clinical Features

The clinical picture varied according to the degree of damage or compression to the brain-stem The best prognosis attended the cases showing hyperpyrexia with tonic fits superimposed on decerebrate rigidity The poorest prognosis was present in the cases which showed complete thermolability and absolute flaccidity save when disturbed by feeble tonic fits Medullary failure was imminent in the thermolabile and flaccid group, the blood-pressure falling and the respirations becoming shallow, irregular, and gasping However, 2 patients with this clinical picture have survived The tendon reflexes are increased in the hyperpyrexial and rigid patients, the plantar reflexes are extensor, whereas in the flaccid state neither tendon reflexes nor toe movements can be elicited.

In the fully developed decerebrate state the patient lies with knees and toes rigidly extended and the ankles plantar-flexed. There is spasm of the femoral adductors and pectorals, the arms are pronated and the wrists flexed, while the elbows are held in a position peculiar to that patient which may be either flexion or extension (fig 1)

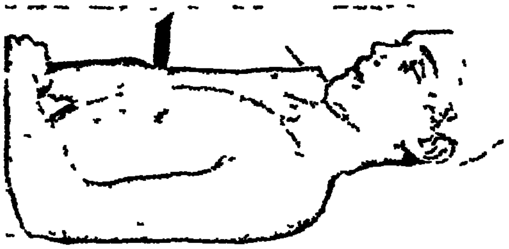

Fig 1—Patient five days after severe head injury, with decerebrate rigidity and hyperpyrexia

Tonic fits, which are merely exacerbations of the spasm described, may be continuous or intermittent They are always associated with a rise of temperature and may be precipitated by external stimulation Partial or fragmentary forms of the decerebrate posture were seen During their recovery 2 patients still showing decerebrate rigidity and pyrexia were able to speak and move the spastic limbs purposefully

A tachycardia of 100–160 developed in all cases within an hour of onset of decerebrate rigidity The breathing was stertorous and the neck veins were distended The patient seemed unable to clear mucus, blood, or vomit from the pharynx (Denny Brown and Ritchie Russell [1941] noted a transient disorder of swallowing mechanisms in concussed cats) In the acute head injury, damage to the vagal nuclei is also partially responsible for this difficulty Vomiting is frequent and usually contains altered blood—sometimes blood previously swallowed but sometimes arising from gastric or œsophageal erosions, which are a common postmortem finding in head injuries of this severity (Maciver et al. 1956) No case of ruptured œsophagus occurred in the treated group, but 2 cases occurred in the control series Absence of bowel sounds were recorded often, abdominal distension occasionally, and retention of urine twice

The pupils were unequal in 16 cases, equal in 6, obscured by orbital hæmatoma in 2, and masked by 3rd-nerve damage in 2 They were reduced in size in most instances and fixed in 19 cases The eyeballs were usually central, but roving movement once, and conjugate deviation twice, have been observed These findings relate to the first examination of the patients

Stage of Coma (one to three weeks)

The signs are a mixture of those due to injury and those due to therapy Muscle hypertonicity is reduced and tonic fits do not occur, the temperature being held steady at 96–98°F Respiration is quiet and free from straining The blood-pressure is usually low on chlorpromazine and tachycardia is constant Weight loss and normochromic anæmia are usual Skin-sensitivity reactions to chlorpromazine and penicillin are often seen, profuse diarrhœa occurred in 4 cases in which tetracycline had been administered The signs of developing bronchopneumonia at this stage are ominous

Stage of Cerebral Irritation

The patient begins to move his limbs purposelessly and thresh around in bed, often screaming in a nerve-racking way The eyes are open and soon appear to be following movements As recovery progresses, movements become more purposeful and noises more like words Pupil size and reactions are normal, and tendon reflexes present and equal in the absence of focal damage, though plantars are often extensor Exceptionally, the decerebrate attitude persists partially (fig 2) Towards the end of this period the patient begins to talk irrationally and can sit up in bed with assistance The tracheotomy has usually healed

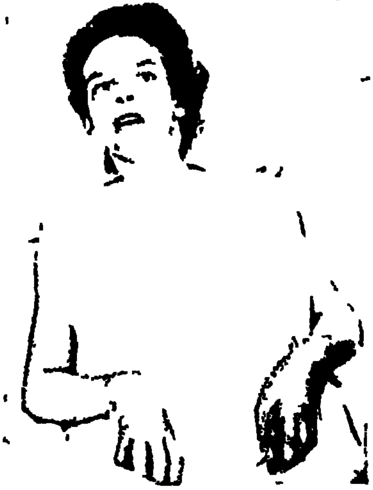

Fig 2—Patient in control series showing persistent decerebrate attitude three months after severe head injury in which brainstem was primarily involved

Stage of Confusion (two to twelve weeks)

This period covers the piecemeal return of mental faculties together with the ability to stand, balance, walk, feed, and make use of the toilet Ability to talk comes early—on the average three weeks after injury—but rational conversation much later The patient is disorientated, often failing to recognise family and friends, and can develop extraordinary delusions to account for his condition and circumstances The average time for walking was six weeks, but 1 patient was mobile after a fortnight When physical recovery outstrips mental, a formidable nursing problem presents The appetite is always excellent and usually ravenous, and weight is rapidly regained Formal neurological examination and assessment of deficit are possible

Treatment

The regime laid down is in no way a substitute for accurate diagnosis and surgery—rather the reverse, for it places within the scope of surgery cases in which the prognosis would otherwise be hopeless A decerebrate picture in a case of acute head injury was always thought in the past to be an unequivocal sign of an injury to the mid-brain In some cases presenting with similar signs, a surface hæmorrhage has been found at operation or at necropsy, Jefferson (1921) drew attention to this fact and suggested that, in any case where a doubt exists, exploratory burr-holes are advisable We would further suggest that routine burr-holes are always advisable to exclude surface collections, particularly subdural hygromas and hæmatomas

Immediate Treatment on Admission

Although speed is not always of prime importance, there are occasions where it is life-saving Where a patient is admitted deeply unconscious in a decerebrate state with inadequate respiratory effort and a rapidly rising temperature, the pupils, long bones, ribs, pelvis, spine, abdomen, and chest should be rapidly examined to exclude fracture, pneumothorax or hæmothorax, and intra-abdominal bleeding

The clothing should then be removed and a drip set up at the ankle 400 ml of sterile water should be mixed with dried plasma of 3 pints of blood, and run as fast as the drip will allow, a specimen of blood for cross matching being obtained at the same time 25 mg of chlorpromazine should be injected into the drip, thus bringing about relaxation in approximately a minute As soon as the jaw relaxes an endotracheal tube should be passed under direct vision, and suction of inhaled blood or regurgitated stomach contents should be instituted, and warm, moist oxygen given A stomach-tube should be passed and the stomach emptied, the tube being retained for further aspirations The head is then shaved and any fractures of the limbs are immobilised The question of tracheotomy and of operation is then discussed, and if this is necessary, it is arranged as soon as the patient's condition is reasonably satisfactory, and as soon as possible regular doses of lytic cocktail are given, usually by drip or by intramuscular injection Apart from triple plasma, blood in our opinion is the only isotonic fluid permissible, and it is given only where associated injuries would necessitate transfusion

The first case treated along these lines was a boy of 16 years, admitted in decerebrate rigidity an hour after being knocked down by a car On admission his temperature was 105 4 F and he was in circulatory failure with Cheyne-Stokes breathing Normally we would have expected death within half an hour, but the use of intravenous triple plasma and intravenous chlorpromazine, exposure to cold air with wet sheets, and the passage of an endotracheal tube changed the picture immediately Within an hour the temperature was brought down to normal and the decerebrate condition was under control When the endotracheal tube was removed a few hours after admission, his condition immediately deteriorated, he became blue and obviously anoxic, and his decerebrate rigidity returned His tube was replaced with immediate improvement, and tracheotomy was carried out as soon as possible with continuing improvement in his condition After five weeks of coma he began to make a satisfactory recovery

Posture

It is important, until at least an endotracheal tube is passed and the stomach contents aspirated, to nurse the patient in the semiprone position with a Trendelenburg tilt of 20°, or even in a knee-elbow position where there is a drainage of blood and cerebrospinal fluid into the mouth and pharynx. Once, however, the patient is intubated or tracheotomy has been performed and the regime commenced, we are of the opinion that the best position for nursing is the supine position without pillows initially, the position being frequently changed, and before suction the patient is placed in the Trendelenburg position for ten minutes to effect adequate drainage. All other positions appear to embarrass respiration. After suction the patient is returned again to the supine position. As the patient progresses a sitting position can be gradually adopted.

Tracheotomy

In the deeply unconscious patient suffering from the effects of a severe head injury, cerebral anoxia is likely to produce profound and irreversible changes in the brain-stem and cerebral hemispheres. In our opinion tracheotomy is the only certain method in the prevention of cerebral anoxia, and in all adult patients it has been our practice to perform this operation as quickly as possible. As has been already indicated, inserting an endotracheal tube may be of value as an emergency procedure, or if early return to consciousness appears likely, but in our opinion no tube should be retained for longer than eight hours. In children tracheotomy may not be as necessary but should be performed at once if indicated. Of 21 adults in this treated series 20 had tracheotomies, but of 5 children only 2 had this operation performed. Once tracheotomy has been performed careful aseptic suction must be applied frequently, and the tracheal tube and bronchial tree must be kept clear. This suction must be adequate but reasonably gentle, and the suction tube should be soft enough to ensure that damage to the lining of the bronchial tree is minimal. The tube should also be long enough to reach to the depths of the tree when required, suction first being applied on one side and the patient then turned so that suction can be applied to the other bronchus. Any oxygen administered should be warmed and moistened so that hardening or coarsening of the secretions is avoided.

The Lytic Cocktail

This cocktail, consisting of chlorpromazine, promezathine, pethidine, and levallorphan, has been used in all cases, but no attempt has been made to produce hypothermia or a hibernating condition.

The cocktail has the following functions:

1. It has made it possible to control temperature with comparative ease, and our aim is to maintain as normal a body temperature as possible.
2. It relieves muscle spasm and abolishes tonic fits, thereby reducing heat production and oxygen consumption.
3. Vomiting is reduced or abolished by chlorpromazine, whilst gastric secretion and intestinal mobility are both markedly reduced, and there is a hope that autonomic disturbance, ulceration and rupture of the œsophagus, or mucosal hæmorrhage may be prevented. Drying of secretions in the mouth and respiratory tract, though a troublesome side-effect in the conscious patient, is highly desirable in the decerebrate state.
4. It enables intubation to be carried out without using a relaxant.
5. It markedly reduces restlessness.
6. It has been found to protect animals against traumatic and hæmorrhagic shock, and Pocidalo and Tardieu (1954) found that it increased survival-time or diminished the severity of lesions produced in dogs by injecting irritant materials into the cerebral peduncles.

Dosage.—Usually each dose of the cocktail contains 25 mg. of chlorpromazine, 25 mg. of promezathine, 25 mg. of pethidine combined with levallorphan; the daily requirement of each of the first three constituents varies from 100 to 300 mg. according to the severity and progress of the case. In certain circumstances the dosage of one of the constituent drugs has been altered—e.g., if the patient is reacting to slight external stimuli by violent tonic fits, it would be reasonable to increase the dosage of pethidine and levallorphan. The cocktail is given at first by intravenous drip in urgent cases, or more usually by intermittent intramuscular injection. It is possible to produce complete flaccidity in all cases if a large enough dose is given, and it may be useful to do this initially so that the temperature can be reduced from dangerously high levels, but such doses appear to depress the respiration and may lead to hypostatic pneumonia if used continuously. It has, therefore, been our object to give a sufficient dosage greatly to reduce, but not to abolish, abnormal tone. At this level the temperature will have to be controlled physically; this is a relatively easy matter.

Complications.—The only constant complication encountered, which was definitely due to chlorpromazine, was drug rash. In the final stage of this regime almost all patients suffered hypotensive attacks lasting twelve to twenty-four hours. These were predominantly systolic falls of 20–40 mm. Hg, but 6 patients required mephentermine or noradrenaline for short spells. These attacks may have been due to the chlorpromazine, but at this stage we were using pethidine without levallorphan, and since changing over to this combination we have had no further trouble. We felt that pethidine alone produced a degree of respiratory depression which led to a fall in blood-pressure due to further anoxia of the medullary centres. Pethidine and levallorphan appear to be completely safe, and, of course, no respiratory depression is produced. Laborit et al. (1955) believe that chlorpromazine causes a shift of intracellular potassium into the cells, and a lowered serum K^+ was a fairly constant finding in the treated group, though in no case did the level fall dangerously low. No severe disturbance of respiratory rate and rhythm was noted after intravenous injection of chlorpromazine in decerebrate cases; in fact return to a more normal state was the rule, although Dobkin et al. (1954) have noted irregularity of rhythm with decreased minute volume.

Cooling

If sufficient doses of the lytic cocktail are given there is little difficulty in lowering the temperature by (1) exposure of the patient with, if necessary, an open window or door, (2) the use of wet sheets, (3) strategic placing of ice-filled rubber bags, and (4) using the more complex circulating coolers. Cooling of the injection site should be avoided, and heavy cooling devices should not be allowed to press on the chest as this reduces tidal volume.

Feeding

This should be intravenous until danger of regurgitation and aspiration is over; this period lasts usually one to four weeks. All intravenous fluids are made hypertonic in the first week by adding 50% dextrose or sucrose. After this period a stomach tube is used until the patient has recovered sufficiently to feed himself. Initially during this period a constant drip of milk and water is given, and this is followed by a once-daily tube feed yielding

2200 calories (protein 100 g, fat 100 g, carbohydrate 225 g) with the following ingredients

Whole milk	40 oz
Eggs	2
Full cream dried milk	3 oz
Soya flour	2 oz
Glucose	4 oz
Salt	gr 2 5
Ferrous sulphate	gr 3
Aneurine hydrochloride	5 mg
Riboflavine	2 mg
Nicotinamide	20 mg
Pyridoxine	2 mg
Calcium	3 mg
Ascorbic acid	200 mg
Vitamin A	4500 I U
Vitamin D	1000 I U

Once the patient's tracheotomy is closed he is given small doses of water by mouth, increasing to milk-and-water mixture and then to a high-protein and high-vitamin diet

Oral feeding is most dangerous because of the incoordination of swallowing mechanisms, and if the patient is encouraged to swallow too soon aspiration into the trachea often ensues

Electrolytes

These should be estimated daily at first, particular attention being paid to serum-potassium A reduction of potassium has been a constant finding, and within twenty-four hours it falls to 8–14 mg With reference to the blood picture 10 out of 16 adults who lived long enough developed anæmia with 10 g Hb per 100 ml or less Hæmoglobin was estimated frequently and, when necessary, blood was transfused

Antibiotics

The bronchial secretion should be repeatedly examined bacteriologically as a guide to the choice of antibiotics Penicillin has usually proved sufficient if given in large doses (1 million units intramuscularly four-hourly) Tetracycline appeared to be very dangerous in 3 cases In the treated group 4 patients who received tetracycline developed profuse and persistent diarrhœa, all had received large doses of vitamins and in no case were pathogenic organisms isolated from the stool 3 of these patients became considerably dehydrated and showed a severe increase in the blood-urea We are of the opinion that, if possible, use of tetracycline should be avoided

Hypertonic Plasma

Intravenous hypertonic fluids cause a fall in the cerebrospinal-fluid pressure, and there is clinical evidence that they can improve the condition of patients with raised supratentorial pressure Hughes et al (1938) introduced hypertonic plasma in an attempt to produce a more sustained effect than that produced by non-colloidal substances and to avoid the rebound to higher pressures They claimed that a sustained fall of pressure can be produced in man, and this was confirmed in animal experiments by Bond et al (1938) We have departed from this method only by giving much larger quantities of plasma solids, 400 ml of sterile water being mixed with dried plasma of 3 pints

The uses of hypertonic plasma are (1) to prevent cerebral œdema, (2) to treat surgical shock, and (3) to reverse coning Pupils which had become fixed and dilated have become normal in size and reaction within fifteen minutes of a drip being started, with a corresponding improvement in respiration and pulse-rate

Concentrated plasma has been used in fatal cases, and at necropsy the brain has appeared much less swollen than in our previous cases where intense dehydration has been brought about by means of restricted fluid intake and mercurial diuretics No serum jaundice or other toxic effects attributable to plasma have been observed In vitro, human red blood-cells incubated in triple-strength plasma at 37°C for an hour showed no hæmolysis or other damage

Results

The control series was collected in retrospect from case-records The dangers of this procedure are appreciated, but some standard for comparison is desirable, and it is difficult to withhold treatment which appears to benefit the patient for academic reasons, however sound

All head injuries admitted under the care of two of us (I N M and L P L) between Jan 1, 1955, and Dec 11, 1956, were reviewed using the same diagnostic criteria as in the treated group—i e, partial or complete decerebrate rigidity with tonic fits and a rising temperature Of 1092 case-records considered, 56 fulfilled the criteria of selection and form the control group The treated group of 26 patients was drawn from a total of 413 consecutive admissions The difference in incidence in the two groups is not significant, so the figures can be pooled for a better estimate, giving for the syndrome an incidence of 5 5% of all head injuries

As a further check on sampling, the incidence of severe associated injuries (other than to the head) was compared in the two groups Such injuries occurred in 10 of the 26 patients in the treated group (38%) and in 16 of the 56 patients in the control group (28%) this difference is not significant ($\chi^2 = 0\ 55$ with 1 df), suggesting that the groups were comparable with respect to the violence of injury Clinical signs other than those used for selections were generally similar in the two groups, but there was a considerable difference in age distribution, the control series containing 19 more children and 3 patients over 61 years To get around this difficulty a "standardised" control group was constructed by applying the death-rates partitioned by age and sex in the crude control group to a hypothetical population with the same age and sex distribution as the treated group

Mortality

Table I shows the mortality in the control and treated groups (see also fig 3)

TABLE I—MORTALITY IN CONTROL AND TREATED GROUPS

Group	Died	Recovered	Total	Mortality (%)
Crude control	39	17	56	69 6
Standardised control	20	6	26	76 8
Treated	10	16	26	38·4

χ^2 between crude control and treated group = 4 7 with 1df
χ^2 between standardised control and treated group = 6·4 with 1df

Mortality in the treated group was 38 4%, in the crude control group (which contained a high proportion of children) 69 6%, and in the standardised control group 76 8% The difference between the mortality-rates in the treated and standardised control group is statistically significant ($\chi^2 = 6\ 4$)

Because of the diversity of type of associated injury and consequently small numbers of each type recorded, detailed comparison of effects has not been attempted However, of those 18 patients in the control group who had no severe associated injury, 6 died, compared with 4 deaths in the 8 who had severe associated injury

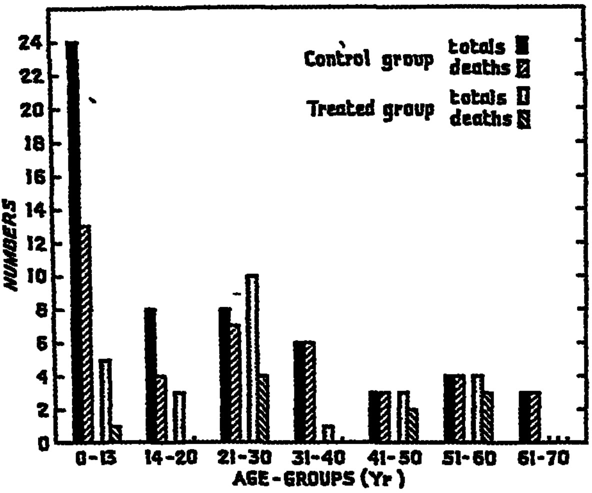

Fig 3—Mortality in control and treated groups

Survival-times

The survival-times of patients who died in the treated and control groups are shown in fig 4 and in table II

TABLE II—SURVIVAL-TIMES MEDIAN TEST

—	Control	Treated	Total
Above median	16	8	24
Below median	23	2	25
Total	39	10	49

$\chi^2 = 3{\cdot}4$ with 1 d.f. (i.e., falls just short of 5% level at 3·8)

Those in the treated group survived longer than those in the control, and by the median test this difference is found to fall just short of significance at the 5% level

The degree of residual disability in those who recovered was assessed during inpatient treatment and at follow-up clinics Of 56 patients in the control group, 17 survived 10 made a good enough recovery to pass as normal, 1 showed a personality change which made him "difficult to manage", 3 were left with a hemiparesis, and 2 of these had, in addition, homonymous hemianopia and a severe speech defect. The 3 worst results were in patients described in follow-up notes as "completely paralysed", "paraplegic, blind, and totally aphasic", and "a complete vegetable" These observations were made at one to two years after injury, when some of the patients were still improving slowly

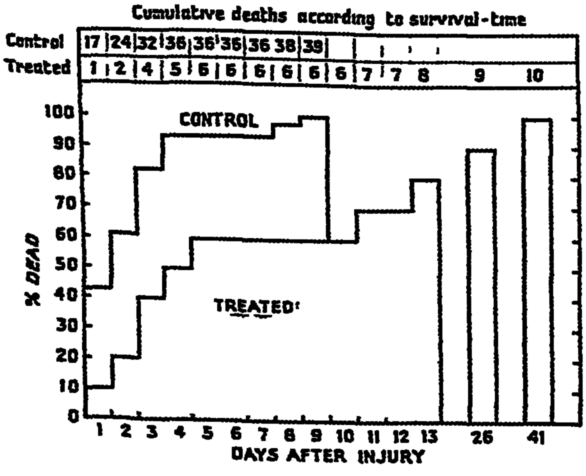

Fig 4—Survival-times in patients who died.

In the treated series, 16 patients recovered out of a total of 26

Follow-up of Patients in the Treated Group

All of the surviving patients in this group are under constant observation and have been submitted to psychological testing at regular intervals

Mental state—2 women have shown fairly pronounced mental changes for some time

One of these, a young married woman of 21, had an intellectual function below average, and there was difficulty in assessing her premorbid intelligence up to February of this year Since then, however, she has made remarkable progress and is now running her own house, and doing her own cooking and shopping, and her memory improves steadily

The other woman, a girl of 19, was very confused and violent for some time Her weight has increased enormously and she is walking well She is unable to read, and mentally, at first sight, she will pass for normal, but under close questioning it is obvious that she is slow in understanding, and we are of the opinion that there is a real deterioration in her intellect, though according to her mother (who has always proved a reliable witness) the girl is improving rapidly

1 man is somewhat euphoric and a little childish but is extremely good-tempered and works well

Physical defects—Relatively few have any physical or neurological deficit apart from the cases mentioned One man is left with definite right facial weakness, and has slight difficulty in eating and speaking because of contracture of his facial muscles He has also lost his sense of smell completely Another man is left, so far, with a permanent 3rd-nerve palsy One woman has a moderate residual left hemiplegia, which is steadily improving, and she is managing well One man has shown a fair amount of irritability and poor memory for recent and past events and has slight weakness of the left leg He also complains of dizziness

Return to work—5 patients have not yet returned to work At present 2 of these are considered fit for light work but have not yet returned 1 is likely to be fit for light work in a month and another in three months 2 patients have returned to light work, and both should return to their normal employment within a reasonable time. 9 patients have returned to their pre-accident occupation and are managing well Important factors influencing prognosis are the age and sex of the patient Children have the lowest mortality and make the best recoveries, this may be because they are less prone to respiratory insufficiency Women also seem better able to survive severe head injuries than men, the survival-rate being 5 out of 9 in the control series and 6 out of 6 in the treated series The injuries in these cases were comparable in severity to those in the men.

Conclusions and Summary

After a severe head injury, decerebrate rigidity and hyperpyrexia, either separately or together, must be regarded as an ominous development A retrospective survey showed that in this type of case the mortality was 77%

Respiratory insufficiency has been treated by immediate tracheotomy and aseptic tracheobronchial toilet, and rigidity and hyperthermia by the use of the lytic cocktail and cooling Cerebral œdema has been prevented or relieved by infusion of hypertonic plasma

The mortality has been reduced to 38·4%, and this difference has been shown to be statistically significant.

With further improvements in technique the mortality could possibly be lowered to 20%, but this will not be achieved unless it is realised that respiratory insufficiency exists from the time of the accident, and steps are immediately taken to counteract it, both during transportation to a hospital or head-injury centre and on arrival at a casualty department

It is likely that in the treated group a high proportion of patients would have died if these recent methods of treatment had not been adopted With the regime described, the majority of patients who recovered have developed little in the way of intellectual deterioration or severe mental symptoms Most of the patients will be fit to return to productive work and will not remain a burden on their family or the community

Our thanks are due to Mr I J C Frew, consultant ear, nose, and throat surgeon, Newcastle General Hospital, for his assistance in our cases and for performing all the tracheotomies at any hour of the day or night, and to Dr J G Matheson and Dr J D Whitby, consultant anæsthetists, Regional Neurosurgical Unit, Newcastle General Hospital, for the interest they have shown and for their considerable assistance But for the magnificent nursing these results could not have possibly been obtained We should like to thank our ward sisters—*Miss W Gault, Miss E Brooks*, and *Miss I Shearer*—for all their help, and the following staff nurses *Miss M Laidlaw, Miss B Brown*, and *Miss D J Jerdan*, who constantly attended our patients This type of treatment puts considerable strain on all the staff concerned, and our thanks are also due to our theatre sisters—*Miss E Hetherington, Miss M White*, and *Miss V Marley*—who have helped us in no uncertain fashion Our thanks are due to Dr S G Owen and Mr Hubert Campbell, who gave helpful advice on the analysis of the results

COLOUR INDEX IN NORMAL SUBJECTS

AS DETERMINED WITH THE AID OF AN AUTOMATIC RED-CELL COUNTER

J C F Poole

D M Oxon

LOCKE RESEARCH FELLOW OF THE ROYAL SOCIETY AND DEPARTMENTAL DEMONSTRATOR IN PATHOLOGY, SIR WILLIAM DUNN SCHOOL OF PATHOLOGY, OXFORD

THE construction, calibration, and performance of an automatic red-cell counter have been described elsewhere (Macfarlane, Payne, Poole, Tomlinson, and Wolff 1958) The object of constructing such a machine was to make accurate and precise red-cell counts a practical possibility in a routine hæmatological laboratory The main purpose of such counts is to make accurate estimates of the amount of hæmoglobin per cell In severe cases of iron deficiency or megaloblastic anæmias this ratio (which can be expressed either as the colour index or as the mean corpuscular hæmoglobin) shows large deviations from the normal value, but because of the great errors of visual red-cell counting (and, until comparatively recently), of hæmoglobinometry) little is known about the variation in the colour index among normal human subjects Such information is required before one can assess the significance of small changes in the colour index, now detectable for the first time

THE COLOUR INDEX OF 24 NORMAL SUBJECTS

Red-cell count (millions of red blood-cells per c mm)	Hæmoglobin (percentage of B S I standard)	Colour index
4 96	99	1 00
4 90	97	0 99
5 58	108	0 96
5 21	106	1 02
4 86	98	1 01
5 05	100	0 99
5 01	102	1 02
4 81	95	0 99
4 46	86	0 97
4 82	99	1 03
4 94	103	1 04
4 96	100	1·01
5 24	100	0 95
5 36	98	0 91
4 85	98	1 01
5 84	107	0 91
5 24	97	0 92
5 17	93	0 90
4 67	88	0 95
5 16	97	0 94
5 01	103	1 03
4 66	97	1 04
4 55	95	1·04

The results of colour-index determinations in 24 normal subjects are here reported

Investigations

Methods—Blood obtained by venepuncture was run directly into glass bottles containing Wintrobe's oxalate mixture in dry form, and mixed well Red-cell counts were made with the apparatus described by Macfarlane et al (1958) and hæmoglobin estimations with an M R C photometer (King et al 1948) The actual photometer used was one in use in the routine hæmatology laboratory of the Radcliffe Infirmary Its calibration is checked frequently and its accuracy can be relied upon

The subjects were adults of either sex Because of the small variation in the results for the whole series there was no advantage in classifying them in any way

Results—The table shows the red-cell counts, hæmoglobin levels, and colour-index values Red-cell counts are expressed as the number of cells per c mm of blood and hæmoglobin levels as percentages of the B S I Haldane hæmoglobin colour standard (B S 1079 1942, see Donaldson, Harding, and Wright 1943) The colour index has been computed in the usual way as the ratio of the hæmoglobin percentage to the red-cell count expressed as a percentage of 5 million cells per c mm The mean colour index is 0 99 and the coefficient of variation for the series is 4 93% The standard error of the mean is 0 0099 The mean value of 0 99 has 95% confidence limits of ±2%

The variation from subject to subject is obviously very small If the error of the mechanical red-cell count contributes a coefficient of variation of 2 5% and that of hæmoglobin estimation 1 6% (Macfarlane et al 1958, Biggs and Allington 1951), the coefficient of variation for a series of colour-index measurements would be expected to be at least 3% if there were no sampling error and no variation from one subject to another As the figure actually found in this series was 4 9% it can be concluded that the variation from subject to subject is so small that, even with the precise instruments now available, it cannot be estimated with any useful degree of exactitude

Discussion

The fact that the mean colour index for normal human subjects turns out to be very close to unity, when determined by the methods described above, is a fortunate coincidence. There is no theoretical reason why it should. We can now infer that the B.S.I. hæmoglobin standard corresponds closely to the hæmoglobin content of blood containing 5 million normal red cells per c.mm. It was not intended to do so when it was set up. Donaldson et al. (1943) aimed at reproducing the colour of Haldane's original carboxyhæmoglobin standard (Haldane and Smith 1900, Haldane 1901). Haldane had prepared a standard supposed to represent the mean level for healthy males. There is no reason to suppose that Haldane failed in his object, but there is reason to doubt whether Donaldson et al. reproduced the colour of Haldane's original standard. Be that as it may, the B.S.I. standard is now known to be about 7% below the mean level for healthy males (King et al. 1944) and must be regarded as arbitrary. If the mean normal colour index had turned out to be much below or above unity the question would have arisen as to whether it might be expedient to redefine 100% of hæmoglobin. Fortunately no such redefinition is either necessary or desirable.

Some clinical pathologists prefer to express the ratio of the hæmoglobin content of blood to its red-cell count as a weight of hæmoglobin per cell (the "mean corpuscular hæmoglobin") rather than as the colour index. No additional information is supplied in this way, since the mean corpuscular hæmoglobin is in effect derived from the colour index by multiplying by a constant. This constant involves a conventional figure for the hæmoglobin equivalent of the B.S.I. standard. As has been argued elsewhere (Poole 1954) the conventional figure at present generally employed is almost certainly inaccurate. Moreover, if a result is reported as the mean corpuscular hæmoglobin, the recipient of the report must know what the normal figure is before he can interpret the significance of any particular figure which may be given. In other words, he must mentally convert the mean corpuscular hæmoglobin into the colour index, a step which could have been avoided by reporting the colour index directly.

Notwithstanding these considerations, the decision as to whether to report results as the colour index or the mean corpuscular hæmoglobin must in practice be dictated by local preferences. In the series reported above the mean value for the mean corpuscular hæmoglobin is 29·4 micromicrogrammes if the hæmoglobin equivalent of the B.S.I. standard is taken as 14·8 g. per 100 ml. of blood, or 28·9 µµg. if the equivalent is taken as 14·5 g. (Poole, 1954). This is very close to the figure of 29·0 µµg. given by Wintrobe (1934), which was the mean of 698 determinations on adults of either sex and which he still regards as the best available estimate (Wintrobe 1956).

The constancy of the colour index in different normal human subjects is striking. Because of the errors of the visual red-cell count, previous information on the variation between different normal subjects is of little value. Indeed Biggs and MacMillan (1948) in a series of replicate counts on the same blood sample, found approximately twice the range that has been found here with 24 different subjects. Because of the small range of normal colour-index figures, there is every reason to hope that small deviations from the normal which can now be detected reliably, will prove significant indications of disease.

Summary

The colour index has been measured in 24 normal human subjects using an automatic red-cell counter and an M.R.C. photometer. The mean value for the series was 0·99 and the overall coefficient of variation was 4·93%.

I thank Sir Howard Florey, F.R.S., for his continued interest in this work, Dr. R. G. Macfarlane, F.R.S., in whose department most of this work was carried out, and Dr. A. H. Tomlinson for much helpful advice and criticism, and Mr. M. J. Allington, F.I.M.L.T., and other members of the staff of the routine hæmatology laboratory of the Radcliffe Infirmary, who collected the blood samples.

PARALYTIC BONE LENGTHENING FOLLOWING POLIOMYELITIS

P. A. RING
M.S. Lond., F.R.C.S.
LAMING EVANS SENIOR ORTHOPÆDIC RESEARCH FELLOW, ROYAL COLLEGE OF SURGEONS OF ENGLAND

B. C. H. WARD
M.R.C.S., D.M.R.
RADIOLOGIST, QUEEN MARY'S HOSPITAL FOR CHILDREN, CARSHALTON, SURREY

POLIOMYELITIS in early years is nearly always followed by disturbance of growth of the affected extremity. The extent of this disturbance, and its associations with muscle paralysis, have been described by Stinchfield et al. (1949), Gullickson et al. (1950), and Ring (1957), who have noted the progressive discrepancy which develops between the two limbs in patients with asymmetrical residual paralysis. The attention of most investigators has been directed towards the shortening which occurs as the child grows, and the early growth of the limbs after paralysis has rarely been studied.

In the course of clinical examination of patients who had contracted poliomyelitis some time previously, our attention was drawn to children in whom lengthening of the more paralysed limb apparently developed, and radiographic studies confirmed that this did in fact occasionally occur. Whether this was a normal feature of limb paralysis was more difficult to determine, although Green and Anderson (1955) have suggested that lengthening may occur in the first year. In examining scanograms of 30 children taken during the first two years of paralysis, Lenque (1956) observed that in 12 the affected limb showed lengthening.

This phenomenon of early lengthening is rarely appreciated, partly because it is slight, partly because it is transient, and partly because the patients are often not ambulant. It is rarely of clinical significance, although occasionally raising the shoe of the unaffected leg may be necessary to maintain a level pelvis and a facile mode of walking.

Material and Method

We have confined our observations to children aged 2–12 years under the care of a single physician at Queen Mary's

Hospital for Children, Carshalton In each case the date of onset (in 1955–57) was known precisely At an initial survey those with little or no lower limb paralysis, whose stay in hospital might be expected to be very brief, were excluded It was our intention to examine and radiograph patients during the first month after onset, and thereafter at three-monthly intervals in the first year and at six-monthly intervals in the second year, a final examination being made two years after onset In fact complete records for the two years could not be obtained, and the conclusions are derived from those patients who were under our observation for six months or more

At each examination the power of the main muscle-groups of the legs was estimated and charted according to the M R C scale, where 0 represents complete paralysis and 5 represents full muscle power The muscles were examined in twenty groups and the total muscle power of the limb was expressed as the muscle score, that of the normal limb being 100 In most patients there was detectable weakness of both legs, and subtraction of the muscle score of the weaker leg from that of the stronger was used to give an index of the difference of muscle power between the limbs The lengths of the legs was measured clinically from the anterior superior spine to the medial malleolus The mid-thigh circumference and the circumference of each calf was measured, and from these measurements the amount of wasting of both thigh and calf was estimated A scanogram of the legs was then taken, and the lengths of each femur and tibia were measured upon the dry film The femur was measured from the top of the head to the intercondylar notch and the tibia from the intercondylar notch of the femur to the upper surface of the talus These measurements were made by one of us without prior knowledge of the extent of the paralysis

Observations

Of the 59 patients with a significant residual lower-limb paralysis there were 11 in whom we could detect no difference between the amount of muscle loss, or between the muscle scores, and these patients have been excluded from this series There were 48 patients with an asymmetrical lower-limb paralysis, but only 2 of these had no detectable involvement of one leg Whilst it is an advantage to have one normal leg as a standard for comparison, it is our impression that strictly unilateral involvement in the early stages of poliomyelitis is relatively rare

There were 113 clinical and X-ray examinations carried out in the 48 patients with asymmetrical paralysis of the limbs For each of the periods after onset a histogram was constructed showing the number of patients in whom the bones of the legs were equal in length and the numbers showing either shortening or lengthening of the more paralysed limb The measurements for the femur and tibia were considered separately, and any detectabl difference between the bone lengths was considered to be of significance It is difficult to define the experimental error of the scanogram, but by expressing the results in this way we hoped that errors of technique and measurement would be scattered evenly between the two limbs

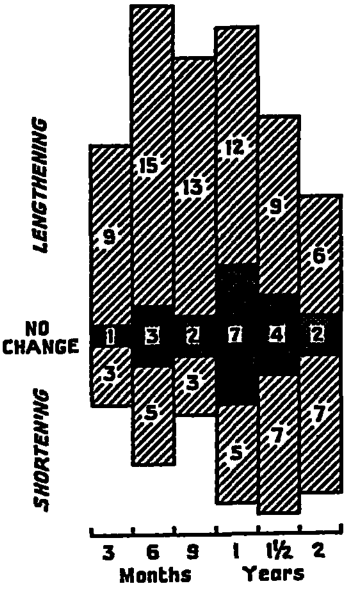

Fig 1—Histogram indicating numbers of patients with tibial lengthening or shortening in the more paralysed leg at varying periods after the onset of the disease

Excluding those in whom the limbs were of equal length, and assuming that inequality of leg length is normally distributed at random, then for the first year after onset $\chi^2=11\ 5$, P−0·02

The measurements of the tibia are shown in fig 1 Three months after onset most of the radiographs showed lengthening of the more paralysed leg, and this change was more distinct in the observations taken at six months and at nine months after onset At the end of the first year, while many of the tibiæ showed lengthening, a considerable number were shorter and the later observations indicated that shortening became progressively more common Grouping together the observations for the first year, 49 radiographs showed paralytic lengthening of the tibia, 16 showed shortening, and 13 showed equality

Observations on the femur for the same period are seen in fig 2 During the first year 38 radiographs showed paralytic lengthening of this bone, 13 showed shortening, and in 27 the bone lengths were equal In the femur, as in the tibia, during the second year shortening became the more common phenomenon In most patients the difference in length between the two bones was slight, and the maximum lengthening of the leg as a whole in this series was 11 mm comprising 3 mm in the tibia and 8 mm in the femur

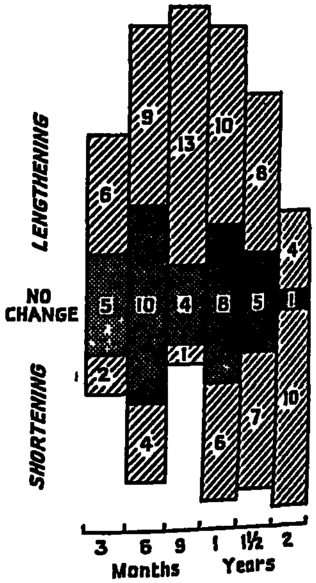

Fig 2—Histogram indicating, as in Fig 1, lengthening or shortening of the femur

For the first year $\chi^2=7\ 65$, P−0 10

The measurements of the patients with asymmetrical leg paralysis have also been examined, to determine the frequency of overall lengthening of the more paralysed limb There were 33 patients for whom there were radiographs taken in the first year after onset Of these, 23 had paralytic lengthening, in 4 cases the legs remained equal in length, and in 6 the legs became progressively shorter We were unable to separate the first from the third of these groups by simple clinical examination There was no difference between the pattern of muscle paralysis in the two groups, nor was there any clinical evidence that a vascular factor distinguished one, the paralysed limb which is longer than its fellow may still be cold and show evidence of cutaneous vascular insufficiency

Discussion

Paralytic lengthening of a limb in the first year after an attack of poliomyelitis occurs in most patients in whom there is a detectable difference between the residual muscle power of the two legs It is a temporary phase, which is almost always followed by shortening Since there is no evidence that the virus of poliomyelitis affects the bone itself, the changes in length must be secondary either to the disturbance of nerve-cells, to the paralysis of muscles, or to changes in the blood-flow of the limb

Damage to nerve cells in poliomyelitis affects primarily the anterior-horn cells, and the motor fibres from these cells have no direct spread to bone The main innervation of this tissue is derived from the autonomic nervous system, and fibres pass in along the vascular channels (Hurrell 1937) In growing bone the osteoblasts themselves may receive a nerve-supply (de Castro 1929) Damage to the sympathetic outflow may produce hyperæmia of bone, as Fell (1949) has shown by experiments in the kitten This hyperæmia may be associated with an increase in the rate of growth (Goetz et al 1955) The rate of growth may also increase after sympathectomy in the child (Harris and McDonald 1936) There is no clinical evidence that sympathetic paralysis of this type occurs in the early stages of poliomyelitis, although the distribution of the lesions would suggest this as a possible factor.

Since it has been shown that the extent of paralysis is an important factor in the disturbances of bone growth which follow poliomyelitis, it is possible that paralytic lengthening may itself be a mechanical change Paralysis of muscles is normally followed rapidly by bone atrophy (Abramson 1948), and there is commonly an inverse relationship between the rate of growth of bone in width and in length In this relationship, however, it is the epiphyseal cartilage that seems to play the dominant role, and it is unlikely that bone atrophy itself could directly influence the rate of growth in length

As a result of the muscle paralysis, changes in blood-flow in the limb undoubtedly occur and the diminution of metabolic demands by the muscle leaves available for the bone a rather greater proportion of the normal blood-supply Thus an internal shunt leading to hyperæmia of the long bones may play a part

Of the possible explanations of paralytic lengthening of bone in the early stages of poliomyelitis, one of the likeliest is that growth in breadth is indirectly associated with growth in length If we are to regard the action of the epiphyseal cartilage as twofold—(1) to add to the growth in length of bone by endochondral ossification, and (2) to add to the width of the cartilage plate by peripheral accretion—then the depression of the latter activity as a result of muscle paralysis may leave available a considerable growth potential The resulting increase in length reaches an equilibrium after a year or so as the cartilage responds to its new environment

Postscript

In describing the lengthening of bones soon after a limb has been paralysed we had the impression that this had only recently been noted We were therefore somewhat chastened to find that Ollier in 1867 also remarked on the same phenomenon

> "Le léger degré d allongement du membre que nous signalons ici n'est pas constant, probablement parce que les troubles de nutrition commencent immédiatement, mais nous l'avons observé une fois chez l homme et très fréquement chez les animaux sur lesquels nous avons expérimenté et dont nous citerons bientôt les observations On constate, dans ces cas-là, une plus grande longueur de l'os, mais un arrêt de développement en épaisseur, l'os s'est allongé en restant plus mince C'est ce que nous désignerons sous le nom d'*allongement atrophique* "

Summary

The growth of the lower limbs in the first two years after an attack of poliomyelitis has been studied in 48 children with an asymmetrical lower-limb paralysis

In the first year after the onset of the disease, of 33 patients observed, 23 showed overall lengthening of the more paralysed limb 6 patients showed progressive shortening of the limb from the onset of the disease

There appeared to be no clinical distinction between these two main groups

In the second year after onset the more paralysed limb was usually the shorter

We are greatly indebted to Dr David Lawson for permission to examine and report on patients under his care, and to Miss M M C Reardon, Miss B Laye, and Miss Stella Poole for their assistance in the organisation of this study This work was assisted by a grant from the National Fund for Poliomyelitis Research

CARBUTAMIDE and tolbutamide have been shown to control diabetes in certain patients who would otherwise require insulin Carbutamide has been regarded by some (Kirtley 1957, Duncan and Baird 1957, Phemister 1957) as too toxic, and tolbutamide, which appears to produce fewer side-effects, has largely supplanted it Tolbutamide, however, is less potent, and because its hypoglycæmic action is of shorter duration it often has to be given thrice daily We report here results obtained in 43 cases with a new preparation, chlorpropamide [N-propyl-N-(*p*-chlorobenzene sulphonyl)urea]

The patients selected for this trial were essentially of the type described by Bertram et al (1955) as most suitable for oral therapy they were less than ten years' diabetic, were over 40 years old, and had taken insulin, if at all, for not more than two years Only 2 patients were obese, although 17 others had been so Diet alone had not sufficiently controlled the diabetes

As in our original investigation of carbutamide (Murray and Wang 1956), the dose of chlorpropamide was 1 g daily at breakfast, but no "loading" dose was given in the first two days' treatment 13 patients were in hospital and 30 were not The outpatients kept records of urine tests (using 'Clinitest') before each of the three main meals of the day This method proved reliable, corresponding well with the results of determining glucose output in twenty-four-hour collections of urine (Murray and Wang 1958) These collections were obtained in most cases on two consecutive days before starting the drug, and again on two days towards the end of a fortnight's treat-

SUMMARY OF CASES

Patients	Response to chlorpropamide	
	Success	Failure
Number treated	28 (8M, 20F)	15 (3M, 12F)
Over 40 at onset of diabetes	27 (96%)	15 (100%)
Previously obese	11 (39%)	8 (53%)
Duration of diabetes		
"New cases" (<3 months)	4	5
<10 years (excluding "new cases")	17	10
>10 years	7	0
Previously taking insulin		
For 2 years or less		
Dose <21 units	1	2
Dose >20 units	1	0
For more than 2 years		
Dose <21 units	7	2
Dose >20 units	3	1
Total	12 (43%)	5 (33%)
Previous history of ketonuria	1 (4%)	4 (27%)

ment At each attendance at the clinic, in the forenoon, the blood-sugar was estimated For the inpatients similar but more frequent observations were made

A satisfactory response to 1 g chlorpropamide daily was obtained in 28 of the 43 patients treated As the table shows, the two groups of patients—successes and failures—were similar except that ketonuria had previously been noted in 4 (27%) of the failures compared with only 1 (4%) of the successes In the successes a satisfactory response was evident generally by the second or third day, and always within seven days (mean 3 2 days), all three daily urine tests being recorded as "blue" or at worst showing an occasional "trace" (¼%) In the successful group the mean blood-sugar level fell from 273 5 mg per 100 ml before treatment to 161 8 mg at the end of two weeks, while in the unsuccessful the comparable values were 364 9 mg and 304 5 mg In these successful cases in which the urinary glucose output was determined as described above, the mean daily output was reduced from 35 5 g to 3 4 g daily, whereas the mean figures for unsuccessful cases were 58 3 g per day before chlorpropamide was given, and 59 6 g at the end of the course Since the mean blood-sugar value and the mean urinary glucose output were higher, before treatment, in the group which failed to respond, it might be supposed that this group were more severely diabetic, but no such difference was apparent clinically For example, one woman who made a rapid and excellent response to the drug had acute symptoms, ketonuria, and a blood-sugar level of 420 mg per 100 ml before treatment was started

Some of the patients had previously received carbutamide or tolbutamide Of the 28 cases responding satisfactorily to chlorpropamide, 3 had had carbutamide, 4 had had tolbutamide, and 8 had been tried with both Carbutamide 1 g daily had proved effective in all, while tolbutamide had given satisfactory results in 9 at a dose of 0 5 g three times daily, but had failed in 3, even at double this dose Among the failures with chlorpropamide 6 had been treated with the other sulphonylureas all had failed with tolbutamide but 3 had responded to carbutamide The impression gained from these few observations is that chlorpropamide is somewhat less potent than carbutamide, but definitely more potent than tolbutamide

In 5 patients who did not respond well to 1 g the dose of chlorpropamide was increased, 4 receiving 2 g daily, and the other 3 g In 3 cases this increased dosage brought satisfactory control Nevertheless these cases have been regarded as "failures", since, for reasons given below, we think it undesirable to exceed 1 g daily

Though there were no serious toxic effects, and neve any evidence of either leucopenia or thrombocytopenia, 9 patients showed side-effects—in 4 cases after the dose had been increased to 2 g The untoward effects were nausea (insufficient to call for abandonment of treatment) in 7 cases, a diffuse erythematous rash in 1, and drowsiness (unaccompanied by hypoglycæmia) in 1 Because of this evidence of toxicity, occurring particularly on highe dosage, we concluded that the dose of chlorpropamide should not exceed 1 g daily, and we are now trying smaller doses Satisfactory results have already been obtained with 0 5 g, but further experience is required before deciding on the best dosage Provisionally we would advise commencing treatment with 1 g daily, taken as a single dose, and reducing this as soon as a good response is obtained In suitable cases this method seems likely to control diabetes while avoiding undesirable side-effects

Conclusions

Chlorpropamide is an effective oral hypoglycæmic agent in the treatment of diabetes, although its action, like that of similar drugs, is somewhat unpredictable

In most cases which respond, a single daily dose of 1 gramme is sufficient, and this amount should not be exceeded If after a few days' treatment, a good response is obtained with 1 g daily, the dose should be reduced—to the lowest level found effective

We wish to thank Dr R H Gosling of Messrs Pfizer for supplies of chlorpropamide ('Diabinese'), and the staff of the biochemical department, Victoria Infirmary, Glasgow, for their willing coopera tion in this investigation

RETENTION OF SODIUM DURING UNDERNUTRITION

WITH A NOTE ON THE RELATION OF THE EXTRACELLULAR SPACE TO GROWTH AND AGEING

Paul Fourman
M D Lond , M R C P
SENIOR LECTURER IN MEDICINE, WELSH NATIONAL SCHOOL OF MEDICINE

Brian McConkey
B M Oxon , M R C P
SENIOR REGISTRAR, ROYAL INFIRMARY, CARDIFF

From the Medical Unit, Royal Infirmary, Cardiff

A RETENTION of water has often been described in undernutrition, and the reasons for it have been much discussed (Sinclair 1948, Keys et al 1950, McCance 1951, Helweg-Larsen et al 1952) On one point all are agreed—namely, that the excess water is retained in the extracellular space It is, however, still a question at issue whether there is an absolute increase in the amount of extracellular fluid (E C F) or whether, there being no change in the absolute amount of E C F , there is a relative increase because the cells have shrunken Precise interpretation of some workers' results is difficult because they have studied hunger œdema, but the problem of hunger œdema is not necessarily germane to that of simple undernutrition, since it may well represent a distinct pathological process Hunger œdema may affect the

TABLE I—AGES, HEIGHTS, AND INITIAL WEIGHTS OF THE EXPERIMENTAL SUBJECTS

Subject no	Sex	Age (yr)	Height (cm.)	Weight	
				kg	% of "standard weight" *
1	M	38	183	90	113
2	M	38	173	97	136
3	F	46	165	82	123

* The standard weight was calculated from the tables of the Association of Life Insurance Directors and Actuarial Society of America, New York, 1912 (Sunderman and Boerner 1949)

serous cavities (Prym 1921) and is not related to the degree of wasting (Brozek et al 1946, Helweg-Larsen et al 1952)

von Uehlinger (1947) suggested that during undernutrition the volume of the E.C.F increased to take up the space left by the loss of fat and protein tissue, and this suggestion was further developed by McCance (1951) The concept is easy to grasp in the case of the lobster, with a rigid shell and therefore a fixed volume to its body (Morgulis 1916) The same idea can without difficulty be extended to the spaces inside the bones of higher animals (Roger and Josué 1900) But, on the other hand, in these animals the elastic skin and soft connective tissues underlying it clearly must permit changes in the volume of their bodies, in fact when muscle atrophies while a limb is inside a plaster cast fluid does not take its place the limb shrinks

TABLE II—COMPOSITION OF THE EXPERIMENTAL DIETS

Subject no	Cals.	N (g)	P (mg)	K (mEq)	Na (mEq)
1	500	4 55	390	31 2	104
2	800	6 89	604	31 2	107
3	500	4 4	421	29 5	106

The calorie contents were calculated from McCance and Widdowson (1946) The chemical composition was determined by analysis.

We have made an experimental study of the gains and losses of the mineral constituents of the body-fluids during a period of undernutrition The results indicate that, although the E C F does account for a larger than normal proportion of the weight of the body in simple undernutrition, this represents a retention of what was already there rather than a gain of E.C F These findings may, we think, be explained very simply by the anatomy of the spaces which the fluid between the cells occupies The same explanation can be extended to cover the alterations in the amount of water in the tissues during growth and ageing

Material and Procedure

Three volunteers were studied Subjects 1 and 2 were male colleagues, they carried on with their normal duties during the experiments Subject 3 was a woman with osteo-arthritis of the hips, she was up during the whole of the day but was not very active All were overweight (table I) They were weighed daily under standard conditions Their experimental diets provided 500 or 800 calories, of which about a quarter was derived from protein and the remainder largely from carbohydrates (table II) Each of the experimental diets was exactly the same every day, but for one week in each experiment potassium citrate (90 mEq daily) was added. Urine was collected daily and fæces in periods of seven or eight days, and the body's gains and losses of N, P, K, and Na were measured. (The results of the balances of Cl had to be rejected because, through an oversight, the diets for analysis had been preserved with chloroform) Insensible losses were not measured Blood was taken, usually twice in each period, for the determination of the packed-cell volume (P C.V), plasma-proteins, and electrolytes The methods have been described elsewhere (Fourman 1953)

TABLE III—THE LOSSES OF WEIGHT AND THE GAINS (+) AND LOSSES (—) OF DIFFERENT ELEMENTS WITH THE EXPERIMENTAL DIETS

Subject no	Duration of experiment (days)	Loss of weight (kg)	Balances			
			N (g)	P (g)	K (mEq)	Na (mEq)
1	24	8 9	− 74 8	−7 52	−100	+153
2	42	12 9	−101 2	−8 89	−385	+287
3	24	5 9	−36·6	−5 33	−147	−36

Results

The clinical and metabolic effects of the diets we used are well known (Evans 1942, Rynearson and Gastineau 1949, Strong et al 1958) The subjects felt well during the experiments and did not become ketotic

TABLE IV—CALCULATED LOSSES OF PROTEIN TISSUE AND OF FAT

Subject no	Total weight loss (kg)	Protein loss (kg)	Fat loss (kg) (by difference)
1	8 9	2 2	6 7
2	12 9	3 0	9·9
3	5 9	1 1	4 8

Table III shows the losses of weight and also the amounts of N, P, K, and Na the subjects had lost or gained at the end of their period of undernutrition As was to be expected (Quinn et al 1954), all three subjects incurred a loss of the constituents of protein tissue, N, P, and K There was an apparent gain of Na of 6 3 mEq per day in subject 1, 7 mEq per day in subject 2, and 1 5 mEq per day in subject 3, the insensible losses account for these amounts (Freyberg and Grant 1937, Newburgh and Leaf 1950) The trend of the balances was not altered by the administration of potassium citrate (compare Duncan et al 1948) The values for the P C V and the other constituents measured in the blood did not change, and there was no evidence of hæmodilution

Discussion

From the analytical results it is possible roughly to apportion the changes in weight to different constituents of the body The balance of Na showed no significant change. This indicates there was no change in the total volume of the E C F

TABLE V—CALCULATED DAILY EXPENDITURE OF CALORIES

Subject no	from protein	from fat	from diet	Total
1	81	2300	500	2880
2	63	1890	800	2690
3	40	1600	500	2100

The losses of nitrogen were accompanied by losses of K and P It may be assumed that the loss of nitrogen represented a loss of protein tissue and not of connective tissue, for the direct analysis of rats has shown that the nitrogen lost in starvation is derived from muscle cells and not stroma (Hagan and Scow 1957)

Losses of K and P on the other hand do not depend solely on losses of protein tissue (Fenn 1939, Homburger et al 1952), and their relation to the losses of nitrogen in our experiments was quite variable We have based our calculation of the amount of protein lost on the losses of nitrogen In muscle 1 g of N corresponds to 30 g of tissue (Reifenstein et al 1945), and on this basis the losses of N corresponded to 2 2, 3 0, and 1 1 kg of tissue in subjects 1, 2, and 3 respectively The remaining loss of weight was presumably accounted for by a loss of fat (table IV)

In spite of the large contribution of protein tissue to the loss of weight in these subjects, it represented but a small gain of calories to their economy (table v) The calculated loss of fat contributed largely to the total output of calories The calculated figure for the total calorie output corresponds well with the expected calorie outputs for these subjects, and supports the interpretation placed on the results

This may be stated as a loss of cell substance and therefore of intracellular fluid—the cells shrink The total volume of E C F does not change, therefore the E C F must form a higher proportion of the total body water This interpretation agrees with the results of Moore et al 1956, and of McConkey (unpublished), obtained by measuring the E C F and the total water of the body by the dilution principle in wasted and normal people

A consideration of the spatial arrangement of the E C F explains why this must be so The E C F consists of the fluid of the plasma, the lymph, and the tissue spaces, the tissue spaces accounting for about half the whole Now the fluid of the tissue spaces is distributed as a thin film on the surface of cells, and in connective tissue (Manery 1954) Connective tissue itself is a watery gel In undernutrition the fat cells of course shrink (Jackson 1925), but there is no change in their total number The muscle cells also atrophy (Jewesbury and Topley 1913, Moulton 1920, Jackson 1925, Adams et al 1953) But all these cells must retain their surrounding film of water, and the volume of the connective tissue probably remains unchanged (Bramwell and Muir 1907, Adams et al 1953, Waterlow and Mendes 1957) Hence, as can be demonstrated by direct analysis, the water content of fat (Sedlmair 1899, Bozenraad 1911) and of muscle increases (von Voit 1866, Mendel and Rose 1912, Waterlow and Mendes 1957) The volume of the blood does *not decrease* (Perera 1946, Henschel et al 1947, Mollison 1946, Walters et al 1947, Sunderman 1947), and it is probable that the volume of lymph, which is at least as great as that of plasma (Abel et al 1938), also remains the same It is clear, then, that in undernutrition the proportion of E C F in the body must increase, though the absolute amount need not In simple undernutrition, we consider that a *relative* increase in the volume of the E C F is a geometrical necessity if each cell is to retain intact its watery environment It is unnecessary to imagine that spaces left by fat have to be filled to preserve " tissue tension "

It may be noted that the variations in E C F with age can also be interpreted on the basis of the geometrical changes in various tissues In infants the proportion of E C F is higher than in adults (Forbes et al 1956, Friis-Hansen 1957), this is largely because their muscles contain a larger proportion of water (McCance and Widdowson 1956) The muscle fibres, and the cells making them up, are smaller than in an adult, and have a larger surface area in relation to their total bulk

After the sixteenth week of embryonic life in the human the growth of muscle is by hypertrophy, and not by hyperplasia, and the total number of fibres and of cells probably does not increase (Adams et al. 1953), hence in the grown muscle the surface area of the cells is smaller in proportion to the total bulk than in infants and the amount of fluid required to bathe them is smaller in relation to the total volume of the tissue Liver on the other hand grows by hyperplasia and the size of the cells does not change appreciably It is not surprising, then, that the composition of the liver does not vary greatly with age (Nishumura and Inakake 1957)

Finally, on the basis of our interpretation, one would expect the proportion of E C F to increase in muscle when it atrophies It does (Eichelberger et al 1958) And in old age, when the fibres shrink, the water conten of muscle increases (Ranke 1865)

Summary

In three moderately obese people the effects of simple undernutrition were studied, in two of them for three weeks, in one for six weeks

They lost protein tissue and fat but they did not gain sodium There was no evidence of an increase in the absolute amount of the extracellular fluid (E C F), though the proportion of E C F in their bodies increased

It is suggested that a relative increase in the volume of the E C F must inevitably accompany wasting, if the cells which shrink are to retain their normal covering film of fluid This concept has been extended to explain the changes in the volume of the E C F which accompany growth and atrophy

This paper was written as a result of a lively discussion at a Ciba Foundation Colloquium (see Colloquia on Ageing, vol 4 Water and *Electrolyte Metabolism in relation* to Age and Sex, *pp* 113, 16 London, 1958)

A large part of the work for the experiments was done in Oxford in 1952, and we wish to express our indebtedness to Prof L J Witts and our colleagues there We are grateful to Prof Harold Scarborough for his advice and encouragement One of us (B McC) received a grant from the endowment fund of the United Cardiff Hospitals

SENIOR LECTURER IN BIOCHEMISTRY

MICHAEL HATHORN
M B, B Sc (Eng) W'srand
RESEARCH ASSOCIATE

From the Department of Physiology, and Schlesinger Organisation Medical Research Unit, University of Natal, Durban, South Africa

ON the high incidence of severe siderosis in Africans there are now two schools of thought The first maintains that iron overload *alone* is the cause of this type of siderosis Its views are summarised by Higginson (1957)

> " The significance of diet in Bantu siderosis has yet to be established. It cannot be stated that dietary pattern (apart from excessive iron intake) is a major factor in African siderosis in this region "

On several occasions Higginson's coworkers have insisted that siderosis in Africans can be explained purely by excessive intake of iron in the food and that " no lesion of the digestive tract or any other organ need be invoked " (Walker and Arvidsson 1953)

The second school of thought, initiated by Gillman and Gillman (1945, 1951), attributes this type of siderosis primarily to an intracellular metabolic disorder, probably started by chronic malnutrition—even though the excessive bodily iron comes, of course, from the *food* Kinney, Hegsted, and Finch (1949) demonstrated that, in rats, at least, uptake of iron from an iron-rich diet varies with other components of the diet

Higginson (1957) wrote

> " In rats fed a diet of maize porridge and sour milk supplemented by iron, I was unable to demonstrate increased iron deposition as compared to a control group on a stock diet "

This was so strongly at variance with other reports (Kinney et al 1949, Finch et al 1950, Rather 1956) that we thought it essential to reinvestigate the relation of a bad diet to dietary siderosis

Experiment and Results

Adult male rats were fed either our stock ration or uncooked mealie meal, 4% ferric citrate was added to the food of half the rats on each diet These diets were fed ad libitum and fresh milk was also made freely available Liver biopsies were done on several rats in each group at 50 or 100 days, and the experiment ended at 156 days The iron contents of the diets, and also of the livers, spleens, kidneys, pancreases, blood, and entire carcasses of the rats, were determined, while iron distribution was studied histochemically in sections of the above and of several other tissues

The iron content of the whole body, and of the livers and spleens, of the groups of rats receiving the different diets is shown in the table The distribution of iron in the livers of experimental and control rats, at different stages of the experiment, is illustrated in figs 1–3

Our observations may be summarised as follows

1 The total body-iron was greater in rats on a mealie-meal diet than in rats on a good stock ration The hepatic and splenic iron were not significantly different

2 The iron uptake both from mealie-meal and from stock diets was considerably increased when iron was added to them

3 The total body-iron of rats on the iron-enriched mealie-meal diet was more than double that of rats on the iron-enriched stock diet Moreover, the hepatic iron in the former group was almost six times that in the latter On the other hand, the splenic iron in rats fed mealie meal plus iron was not quite twice that of rats fed the stock diet plus iron The table also shows that the contribution of hepatic iron to the total body-iron varied from 6 to 12% in all groups except the rats fed mealie meal plus iron In the latter, hepatic iron constituted 37% of the total body-iron, clearly indicating the predilection of the liver to siderosis, in this dietary setting The histochemical data fully substantiated these chemical findings

4 Another notable finding, not hitherto reported in experimental siderosis in rats, was that in the milder (earlier) degree

CONCENTRATION OF IRON IN LIVER, SPLEEN, AND TOTAL BODY

Diet	No of rats	Daily intake *		Concentration of iron (mg per 100 mg wet weight) in			Ratio of total liver-iron to total body-iron
		Food (g)	Iron † (mg)	Total body ‡	Liver	Spleen	
Stock	5	23	18	8 2±0 5 §	32 3±2 5	115±15 4	0 12±0 01

§ Standard error of the mean
‖ Note greater concentrations of tissue iron despite lower daily iron intake, as compared with group on stock diet + iron citrate.

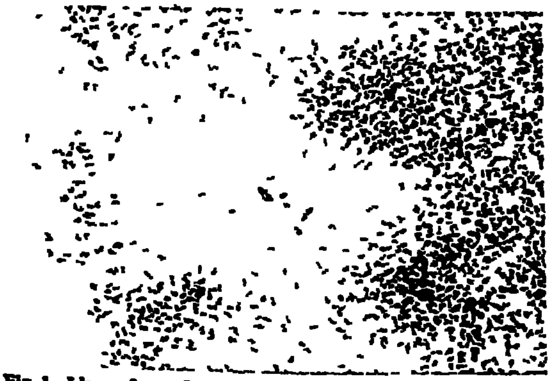

Fig 1—Liver of rat after 50 days on mealie-meal diet enriched with iron, siderosis (dark staining) of liver cells especially around portal tracts. Only a few Kupffer cells near the central vein contain iron. (× 76)

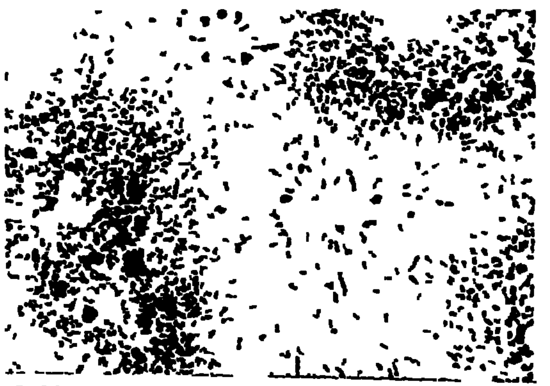

Fig 2—Liver of rat after 156 days on mealie-meal diet enriched with iron Massive siderosis with clumping of iron-containing granules in liver cells in portal half of each lobule Siderosis and clumping of siderin in sinusoidal and portal phagocytes is well marked (× 76)

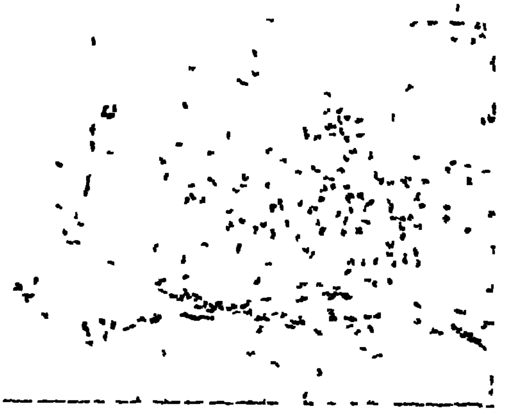

Fig 3—Liver of control rat fed good stock diet plus ferric citrate for 156 days Siderosis absent, only small amounts of iron being detectable in a few sinusoidal and portal phagocytes (× 76)

of siderosis the excess iron within the liver was at first confined to the liver cells themselves Only later, when the hepatocellular iron granules became very numerous, large, and clumped, did sinusoidal and portal phagocytes become laden with iron—possibly through ingestion of effete iron-laden liver cells This finding, in rats, exactly conforms with that noted first by Gillman and Gillman (1945, 1951) and later by Wainwright (1957) and by us (Gillman 1957, Gillman, Hathorn, and Lamont 1957, Gillman, Lamont, Hathorn, and Canham 1957), in the early stages of African siderosis

Comment

Thus, not only did the (defective) mealie-meal diet promote significant increases in the uptake of iron (especially from an iron-enriched diet), but this iron was usually detected, initially, within the liver cells It therefore seems that—as in the African, so too in rats—only when hepatic siderosis is gross may large amounts of iron be found in hepatic reticuloendothelial cells or in the epithelial and parenchymal cells of other organs—apart from spleen, bone-marrow, lymph-nodes, and intestinal mucosa

It remains to be determined whether the excessive iron uptake of rats on a bad diet is a function only of the associated unfavourable ratios of iron, calcium, or phosphate Iron uptake is known to be affected by dietary phosphate (Hegsted et al 1949) and dietary calcium (McCollum et al 1939, Chapman and Campbell 1957) The role of other dietary components such as phytate and protein (Rather 1956) also merits further study

We also want, once again, to focus attention on disturbances in intracellular metabolism as a possible basis for excessive iron uptake It has been shown for humans (Gillman, Mandelstam, and Gillman 1945, Gillman and Gillman 1951), and now (in the present study) for rats, that iron absorbed in excess from the food is initially deposited within the liver cells themselves, and not in the reticuloendothelial system In the African such hepatocellular iron deposition was shown by Gillman and Gillman (1944) to occur first in relation to mitochrondria which are now generally accepted as important foci of cell metabolism These observations are now supported by Richter's electron-microscope studies indicating that hepatocellular iron is derived from altered mitochondria or " siderosomes " (Richter 1957)

Of particular importance, in this regard, are the findings that anoxia—induced by hæmorrhage (Bothwell and Finch 1957) or decompression (Smith et al 1957, Colehour et al 1957)—increases the uptake of dietary iron, and the iron content and total iron-binding capacity of the serum The increased iron-binding capacity, so striking a phenomenon in siderotic Africans (Gillman, Lamont, Hathorn, and Canham 1957), may perhaps be one expression of seasonal nutritionally induced metabolic anoxia Moreover, these effects of anoxia are much greater in older rats than in young ones (Garcia 1957) This last finding may have as its clinical counterpart the fact that definite siderosis has not yet been observed in Africans under the age of about 14

Because of these findings, and the frequency of anoxic changes in hepatic cells in malnourished adult and infant Africans (Gillman and Gillman 1949, 1951) as well as in our experimental rats, we are now investigating the possibility that some form of cellular anoxia, induced perhaps by chronic malnutrition, may promote the prolonged excessive iron uptake, with consequent severe siderosis, so commonly found among Africans in the Union Our *preliminary findings indicate that intermittent decompression* ($1^1/_2$ hours twice weekly at about 360 mm Hg) promoted rapid and marked increases in hepatic iron, especially in rats fed the mealie meal but not the stock diet—both iron-enriched A similar but less marked trend was also noted when the calcium and phosphate contents of the two diets were equalised These findings are in line with recent evidence of the importance of intracellular iron-containing enzymes even in " iron-deficiency " states Beutler (1957) demonstrated a fall in the concentration of several of these enzymes in liver and kidney, long before anæmia was notable, he implied that the symptoms of anæmia may not be attributable solely to the decrease in oxygen-carrying powers of the blood, resulting from the low hæmoglobin, but rather to preceding and persistent derangement in intracellular iron enzymes and consequent impairment in cellular oxidation processes Even the hepatocellular iron deposits described in megaloblastic anæmias may, as suggested by Gillman and Gillman (1951, p 343) be the result of intracellular enzymic changes

Conclusion

Our present results support those of several other similar experiments in the literature showing that dietary iron overload *alone* does not readily induce severe parenchymal cell siderosis if the basal diet is good Also, a bad diet rich in iron produces much more severe siderosis than one low in iron

ULCER UNDER THE RIBS

J H SHOESMITH
M.B. Leeds, F.R.C.S.
SENIOR REGISTRAR, DEPARTMENT OF THORACIC SURGERY,
THE GENERAL INFIRMARY, LEEDS, 1

IF, after a partial gastrectomy or gastrojejunal anastomosis for a peptic ulcer, the patient is unfortunate enough to develop an anastomotic ulcer, it may cause pain just above or just below the left costal margin This may lead to difficulty in diagnosis

Case-reports

Case 1—In January, 1957, a man aged 60 was referred to the thoracic department of the Bradford Royal Infirmary with recurrent peptic ulceration.

He had a duodenal perforation sutured in 1951, a partial gastrectomy in 1952, and a higher gastrectomy with Roux-en-Y reconstruction for stomal ulcer in 1955 In 1956 he developed a gastrojejunocolic fistula, and the colon and stoma were freed and each closed separately Vagotomy was attempted but abandoned After some improvement he began to deteriorate and to lose weight

The most striking feature of the history was severe attacks of intermittent pain These were localised to the left costal margin, to the præcordium, and occasionally to the left shoulder, the left arm, and the left side of the neck. The pain was so severe that he required regular doses of pethidine A barium meal in February, 1957, showed a deep ulcer penetrating the diaphragm

The patient was explored through a thoracoabdominal incision The tissues beneath the diaphragm were very œdematous, and, on separating the stomach remnant, an ulcer 5 cm in diameter was found penetrating the diaphragm and involving the chest wall The ulcer had also penetrated the spleen, and it was adherent to the transverse colon and to the jejunal loop The stomach remnant and the spleen were removed and the jejunal loop was brought up behind the transverse colon and anastomosed to the œsophagus

Postoperative recovery was satisfactory, and six months later the patient was free from pain

Case 2.—A man aged 63 was transferred to the thoracic department of the Leeds General Infirmary in September, 1956

In 1951 he had undergone a partial gastrectomy with antecolic gastrojejunostomy for a longstanding duodenal ulcer After eighteen months he developed an anastomotic ulcer which was treated medically for two years A laparotomy was then done with a view to higher partial gastrectomy, but, because of dense adhesions to the undersurface of the diaphragm, this was abandoned. A transthoracic vagotomy was performed instead

A few months later the pain returned it was severe and situated in the left hypochondrium and above the left costal margin. It was not relieved by food or by antacids A barium meal showed a huge anastomotic ulcer crater

On exploration through a left thoracoabdominal incision the omentum was seen to be adherent to the costal margin of the left diaphragm On attempting to dissect off the stomach and the anastomosis from the diaphragm a large ulcer crater was opened. It measured 5×4 cm, and it was 2 cm deep Its base involved the 6th and 7th costal cartilages and the intervening intercostal bundle A total gastrectomy was performed, together with excision of the stoma and jejunum to beyond the ulcer A Roux loop was fashioned to restore intestinal continuity Convalescence was satisfactory, and a year later the patient was free from pain and gaining weight.

Case 3—A man aged 49 had a partial gastrectomy in 1951 for an old duodenal ulcer Seven months later he began to complain of epigastric pain after meals It was situated in the left hypochondrium, and it was not relieved by food or alkalis Repeated radiological investigations were negative until June, 1954, a probable anastomotic ulcer was then demonstrated.

At *laparatomy* a stalk of fibrous tissue, 1 cm thick, was found, connecting the jejunum distal to the anastomosis to the anterior abdominal wall just below the costal margin The stalk was divided, and, after dismantling the anastomosis, the jejunum containing the ulcer was excised and an end-to-end anastomosis was carried out A higher partial gastrectomy and vagotomy were then performed

Postoperative recovery was satisfactory The man is free from pain and enjoying good health four years later

Case 4—A man aged 49 had a Bancroft partial gastrectomy in December, 1952, for a duodenal ulcer of fifteen years duration. On the seventh postoperative day he complained of stabbing pain under the left costal margin, worse on movement, it was relieved for a time by food or drink but there was severe hyperæsthesia over the affected part Treatment with local anæsthesia brought no improvement. A barium meal was reported as normal

Six months later the patient was still complaining of pain under the left costal margin, particularly when his stomach was empty, and, by January, 1954, antacids had lost their effect A barium meal at that time suggested a jejunal diverticulum only two months later did it show an ulcer crater This appeared to extend from the region of the anastomosis forwards towards the parietes

In May, 1954, a large jejunal ulcer was found at operation 5 cm. proximal to the stoma. It had perforated the diaphragm to involve the chest wall The jejunum containing the ulcer was excised, leaving the base of the ulcer behind and an end-to-end anastomosis was performed. A further partial gastrectomy and vagotomy were then done

The postoperative course was uneventful, and the patient is well and free from pain four years later

Case 5—A woman aged 48 had a cholecystectomy and a posterior gastrojejunostomy for a duodenal ulcer in 1954 In January, 1956, she began to complain of periodic pain in the epigastrium, often related to food A barium meal showed an anastomotic ulcer, and, at operation, a large ulcer was found in the efferent loop A partial gastrectomy with an antecolic gastrojejunostomy and a lesser-curve valve was carried out A week later she complained of pain in the left hypochondrium and under the left costal margin, and four days later she had a hæmatemesis of 20 oz A barium meal before discharge raised the suspicion of an anastomotic ulcer

Despite strict medical treatment the patient complained of intermittent pain under the left costal margin, in the left chest posteriorly, and in the left shoulder The pain gradually became more persistent it was aggravated by deep breathing and heat, and it was not affected by food In October, 1956, a barium meal showed a large penetrating anastomotic ulcer extending forwards

A further operation was performed through a left thoracoabdominal incision On opening the diaphragm an ulcer 3 5 cm in diameter was found in the anterior wall of the jejunum, opposite the anastomosis, it penetrated the diaphragm at its attachment to the costal margin The ulcer was dissected off the diaphragm, leaving the ulcer base behind on the chest-wall the ulcer-bearing segment of the jejunum was then removed, and a subtotal gastrectomy and vagotomy were carried out

The postoperative course was uneventful, and the patient was free from pain a year later

Discussion

Adequate partial gastrectomy results in a small gastric stump, the line of anastomosis usually lying deep to the diaphragm In such circumstances recurrent anastomotic ulceration may involve the diaphragm or occasionally the parietes just below the left costal margin In the latter event the pain becomes parietal and loses its usual relationship to eating The patient, moreover, becomes so concerned about the pain under the ribs that he tends to minimise or forget his indigestion

When the ulcer is so low that it involves the anterior abdominal wall—as used to happen when antecolic gastroenterostomies were commonly performed—there should be little difficulty in diagnosis If, however, the ulcer involves the left costal margin, either just above or just below the diaphragm, the symptoms become more difficult to interpret Pain is then referred to the left shoulder and to the back, and it is influenced by coughing, sneezing, and movement rather than by food or antacids The pain waxes and wanes as in an ordinary peptic ulcer, but some of the exacerbations are extremely severe Two of the patients needed opiates to relieve it If its cause remains undiagnosed the patients may become so disturbed as to develop bizarre symptoms thus in three of the cases neurosis was seriously *considered in the differential* diagnosis

In cases 4 and 5 the pain under the left costal margin appeared in the early postoperative period, it is debatable whether it was a symptom of an extremely early anastomotic ulcer or of a small leak Illingworth (1953) mentions the occurrence of anastomotic ulcers a few days after operation, but a small leak with local abscess-formation and subsequent fibrosis could simulate it

Summary

After an adequate partial gastrectomy the anastomosis lies deep to the left diaphragm, and an anastomotic ulcer may penetrate the diaphragm and involve the chest wall

Five cases are presented they illustrate that such ulcers are liable to cause severe parietal pain in the region of the left costal margin

The diagnosis may have to be made despite this misleading localisation and often without abnormal radiological findings

I wish to thank Mr J Davidson, Mr G H Wooler, and Mr A J C Latchmore for permission to publish these cases and for their help

ASSISTANT PHYSICIAN TO THE WHITTINGTON HOSPITAL

We have recently used a liver-biopsy needle described by Menghini (1957) This preliminary communication is based on our experience of 83 biopsies

Needle

The needle, 7 cm long, is made in diameters of 1 mm, 1 5 mm, and 2 mm (fig 1)

The profile of the tip is original it has an angle of 45° at its end, and is anteriorly convex This facilitates the cutting and aspiration of the biopsy tissue

The conventional stylet or trocar is replaced by a blocking-pin towards the head of the needle, this is 2 cm long and 0 2 mm smaller in cross-section than the internal lumen of the needle The blocking-pin allows the passage of fluid to and fro but prevents the aspiration of liver tissue into the syringe and hence minimises fragmentation of the biopsy *material*

Technique

The technique is biopsy by aspiration The patient either lies supine in bed with the right side near the edge, or half-inclined on the left side The intercostal route in the mid-axillary or anterior axillary line in the right 8th or 9th intercostal space is preferred After local infiltration with 2% procaine a nick may be made in the skin with a scalpel The biopsy needle is attached to a record syringe which contains *about* 2 *ml* of *normal saline First* the *needle* is thrust into the subcutaneous tissue to an appropriate depth prefixed by an adjustable guard, and 1 ml normal saline is injected to free the needle of any subcutaneous tissue which might block its tip

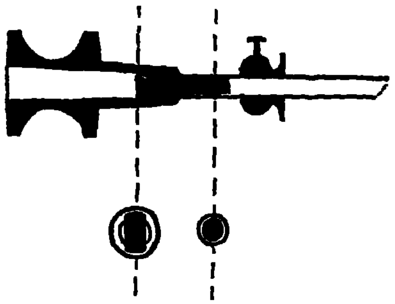

Fig 1—Liver-biopsy needle

The guard is now moved backwards 3 5–4 cm from the tip The patient holds his breath in expiration, and with constant suction at the syringe, the needle is advanced quickly into the liver It is then rapidly withdrawn

The remaining 1 ml of normal saline in the syringe helps to deliver the cylinder of liver tissue thus obtained *into* a container The puncture wound in the skin is sealed with collodion With the right elbow resting against the biopsy site to apply hæmostasis, the patient now lies on the right side for thirty minutes

Outpatients, who were admitted *for* biopsy in the morning, were fit for discharge the same evening

Liver biopsy was done where liver dysfunction needed confirmation, in unexplained hepatomegaly with normal liver-function tests, and in suspected miliary granulomatous conditions or amyloidosis The biopsy material varied from 0 5×0 1 cm to 4×0 1 cm in size it usually included a fair sample of liver tissue (fig 2) On 5 occasions the tissue was fragmented In 25 cases no *portal tracts were included in the* sections

The biopsy provided a definite diagnosis in 23 cases fatty change, and other non-specific changes were seen in 42, and normal liver tissue was obtained in 18

In a review of 20,016 hepatic biopsies from the literature Zamcheck and Sidman (1953) reported an incidence of 0 28 % of major complications Of these hæmorrhage was the most

Fig 2—Portion of liver obtained with needle (× 115)

serious it was often fatal Terry (1952) related the incidence of hæmorrhage directly to the increased bore of the needle The risks of liver biopsy have now been minimised by the reduced size of this needle and by the simplicity and speed of the technique employed Menghini, in a series of 500 biopsies with this needle, encountered no complications

In our experience so far, results of biopsy by this needle have been satisfactory There were no complications except for shoulder-tip pain in 1 case

Our thanks are due to Dr G Menghini, Institute of Clinical Medicine, University of Perugia, for demonstrating the technique and for providing us with the needles

Preliminary Communication

SKIN TRANSPLANTATION IMMUNITY IN RELATION TO HYPERSENSITIVITY

ALTHOUGH the distinction may eventually prove to superficial, it is at present useful to divide immunolog reactions into two classes—those mediated thro orthodox humoral antibodies, and those which seem depend upon the intercession of activated blood-bo e cells To the former class belong all states of immunity that can be transferred from one animal to another serum, to the latter—a class which includes the d allergies and bacterial allergies—belong the states sensitivity that can be transferred only by lymphoid cells There is strong evidence that the reaction provoked homografts of skin (and perhaps by all other "solid homografts that make direct vascular and lymphatic connections with their hosts) is put into effect by a cellular rather than a humoral mechanism [1–7]

It is characteristic of the "cellular" immunities that they manifest themselves in the guineapig and in man as dermal hypersensitivities of the delayed type Our purpose here is to show that the reaction against skin homografts in the guineapig can likewise be made to express itself as a dermal hypersensitivity, and that the state of hypersensitivity can be transferred by activated lymphoid cells but not by serum

A typical experiment made use of two guineapigs from outbred stocks—a donor (D) and a recipient (R) Four skin homografts from D, with a total area of about 6 sq cm, were transplanted to one side of the chest of R, a position in which the regional lymph-vessels drain into the axillary nodes The pairs chosen for ordinary experimental purposes were those in which the homografts broke down in less than 12 days Two reactions could thereupon be demonstrated (*a*) the *direct reaction*, in which antigenic matter extracted from the tissues of D was injected intradermally into R, or (*b*) the *transfer reaction*, in which cells expressed from the regional lymph-nodes of R were injected intradermally into D Both reactions were marked by the development of a tuberculin-like inflammatory response with a latent period of 5–8 hours and a maximum at 24–48 hours

MATERIALS AND METHODS

The guineapigs were either outbred albinos (usually so chosen that animals D and R came from different breeders) or members of an inbred strain—the Heston strain—which has been proved by skin-grafting tests to be for all practical purposes homogeneous The technique of skin grafting has been described by Billingham and Medawar,[8] and the behaviour of skin homografts in guineapigs has been the subject of a general study by Sparrow [9,10] Guineapig R can be sensitised with tissues other than skin, but the use of skin homografts is desirable (*a*) because their donor can be kept alive, and (*b*) because they provide an outwardly visible record of the degree of immunity of the recipient, so that it is possible to eliminate or make special use of the "weak reactors" in which homografts survive for upwards of 15 days

Cell-free antigenic matter was extracted from the spleen or lymphnodes of guineapig D by the method described by Billingham, Brent, and Medawar [11]

In bare outline, cells expressed from the lymphoid tissue of the donor were washed successively in 0 15*M* NaCl, 0 05*M* NaCl, and water, and then rendered into a solution in water by exposure to ultrasonic irradiation The concentration of NaCl was restored to 0 15*M* and the precipitate of desoxyribonucleoprotein, together with miscellaneous cellular debris, removed by centrifugation for 10 min at about 2000 g The solution, now wholly free from cells or large particles, was then spun at 25,000 g for 60 min, the supernatant fluid, containing the soluble protein of the cell and other solutes, was discarded, and the sediment resuspended in Ringer-phosphate at such a concentration that the matter extracted from 1 0 g wet weight of splenic tissue was contained within 2 0 ml of the final suspension (1 0 g wet weight of splenic tissue yields about 10 mg dry weight of final sediment) The suspension is strongly opalescent and, when made from splenic tissue, has a brown or beige tinge that is a minor nuisance when interpreting weakly positive results

Antigenic substances so prepared are "complete" antigens in the sense that experiments on mice have proved them capable of giving rise to a state of sensitivity indistinguishable from that produced by an equivalent dosage of living cells administered by the intraperitoneal route

Antigenic matter was injected intradermally, in volumes of 0 1 ml, into the outer aspect of the thigh of R. The quantity injected represented the matter extracted from 50 to 5 mg initial wet weight of lymphoid tissue (i e, about 0 5 mg to 0 05 mg final dry weight)

Cellular suspensions from the "immune" regional nodes used in the transfer reaction were prepared by teasing out the nodes under about 0 5 ml Ringer-phosphate and adjusting the concentration of cells to about 100 million per ml The cells were injected in fluid volumes of 0 05 ml. and in numbers ranging from 4–6 million downwards

The results of both the direct and the transfer reactions were scored against an arbitrary scale (+ to +++++) which took account of the area of inflammation and of its intensity in terms of reddening, hardness, and swelling

RESULTS THE DIRECT REACTION

The "direct reaction" was described above as the reaction that is produced by the intradermal injection into a sensitised recipient (R) of antigenic matter extracted from the tissues of the homograft donor (D)

Thirty independent trials of the direct reaction gave positive results of variable intensity, three others were negative or marginally positive, but the recipients proved

to be pregnant and must therefore be discounted * Animals which gave a +++++ response after injection of the antigen extracted from 50 mg initial wet weight of D splenic tissue still gave perceptibly positive responses (+ or ++) to the injection of one-tenth of this quantity The weakest positive response elicited by a high dose of antigen was ++ evidently there were wide variations in the degree of sensitivity of the recipients, though all had rejected their skin homografts within 12 days of transplantation Experience with mice, however, has shown that even over a wide range of antigenic dissimilarities between donor and recipient the survival-times of homografts may still fall within the range 9–12 days [14]

The histological appearance of a 24-hour reaction site—kindly interpreted for us by Dr P G H Gell—was essentially similar to that of a tuberculin reaction

Living donor cells—preferably lymphoid cells—may be used instead of cell-free extracts to elicit the direct reaction The reactions were more intensely red and compact than those elicited by cell-free extracts, but table I, based upon three *independent trials, shows that their variability from one animal* to another was just as great The intradermal injection of donor serum into sensitised recipients was ineffective

TABLE I—VARIATIONS BETWEEN THE RESULTS OF THREE TRIALS OF THE DIRECT REACTION (SEE TEXT) USING LIVING D CELLS AS SOURCE OF ANTIGEN CELL DOSAGES EXPRESSED IN MILLIONS

Experiment	Cell dose	Score	Experiment	Cell dose	Score	Experiment	Cell dose	Score
55	15	++++	57	30	+++	58	12	+++++
	5	+++		7 5	++		6	+++++
	1 6	++		3 8	±		3	+++
	0 5	+		1 9	±		2	++
	0 16	+						

The dermal hypersensitivity of four R guineapigs which had each been immunised by four D skin homografts was not strengthened by repeated weekly injections of 2 5 ml of D blood, in one animal certainly, and possibly in two, the intensity of the reaction declined This result has raised in our minds the possibility of a "desensitisation" brought about by the action of humoral antibodies Variations from one pair of guineapigs to another are to be expected, just as the ease of producing "enhancement" varies from one pair of mouse strains to another in accordance with their genetical constitution at the H-2 locus [15]

It has not been possible to demonstrate the direct reaction in the general body skin or foot pads of mice belonging to several different strains, the results with rabbits have been variable and inconclusive

As controls for the specificity of the direct reaction, high doses of cell-free antigen were injected intradermally into thirteen non-immune guineapigs, and up to 6 million normal (non-sensitised) lymphoid cells were injected into thirty-seven others Most of the injections elicited no reaction, a small minority secured a maximal score of ± These are not precise controls, for the *inflammatory* response provoked by the intradermal injection of antigen might be a non-specific consequence of the state of sensitivity as such Two exact controls took the form of sensitising an inbred (Heston) guineapig *with skin* homografts from a non-inbred donor Although in a sensitive state, the inbred recipient failed to respond to an intradermal injection of antigen extracted from the spleen of a Heston donor, that the antigen itself was active was proved by its power to elicit a strong reaction after injection into a non-inbred guineapig which had been sensitised by skin graft from a Heston donor Hence the direct reaction does no merely depend upon the existence of a state of sensitivity depends upon the existence of a state of sensitivity directe against the antigens used in the skin test

TABLE II—RANGE AND DISTRIBUTION OF SCORES OBTAINED IN THIRTE INDEPENDENT TRIALS OF THE TRANSFER REACTION REGIONAL CONTRALATERAL NODES THE NUMBERS ARE THOSE OF THE EXPER MENTAL ANIMALS

RESULTS THE TRANSFER REACTION

The "transfer reaction" was described above as th reaction that is produced by the intradermal injectio into a homograft donor (D) of cells expressed from th regional lymph-nodes of a sensitised recipient (R)

The transfer reaction produced by the injection of 4– million sensitised lymphoid cells is stronger than th direct reaction produced by the injection of concentrated antigenic extracts it tends to reach its maximum a little later (48 hours as opposed to 36) and to last longer, to be more compact and to give rise to redder, harder, and more prominent swellings In its extreme form (scored higher than +++++) the reaction may proceed to limited central necrosis

The scores of thirteen independent trials of the transfer reaction are summarised in table II We are unable to account for the one animal from which no response of any kind was secured The evidence of Mitchison [2] and of Billingham, Brent, and Medawar [3] had led us to expect that the reactions elicited by cells taken from the *contra*lateral lymph-nodes would be very feeble In three of four trials, however (table II), they were just as strong as the reactions elicited by cells from the homolateral (regional) nodes

Among pairs of guineapigs (D and R) chosen at random it sometimes happens that homografts transplanted from D to R live longer than the usual 9 or 10 days these are the "weak reactors" referred to in the section on Methods, and they have made it possible for us to show that the ability of lymph-node cells to elicit the transfer reaction does indeed depend upon the state of sensitivity of the animal from which they were taken

TABLE III—TRANSFER REACTION SCORES OBTAINED IN THE DONORS OF "WEAKLY REACTING" PAIRS (SEE TEXT)

Experiment	Homograft survival-time D→R	Day of transfer of cells, R→D	Maximum score
24	17	17	+–
53	20–25	30	±
54	20–25	30	+
33	40–42	17	±
39	>>30	18	0

The tests summarised in table III were carried out either before or immediately *after these unusually long-lived homografts* had broken down the transfer reactions were feeble or absent

The transfer reaction in rabbits (*unlike the direct reaction*) is particularly violent and long-lasting All experiments with mice have given negative results, regardless of whether the skin at the time of injection was quiescent or *in the midst of a* cycle of hair growth

---

* Pregnancy is known to prolong the survival of homografts in rabbits [12] and to subdue the inflammatory processes that accompany the breakdown of homografts in mice [13] Its effect upon transplantation immunity in guineapigs is not yet known

12 Heslop R W Krohn, P L, Sparrow, E M *J Endocrin* 1954, 10, 325
13 Medawar, P B, Sparrow, E M *ibid* 1956, 14, 240
14 Billingham R E, Brent, L, Medawar, P B, Sparrow, E M *Proc roy Soc B*, 1951, 143 43
15 Snell, G D *J nat Cancer Inst* 1954, 15, 665

It is a matter of great theoretical importance to determine whether or not the transfer reaction can be provoked by *serum* taken from sensitised recipients

Fifteen independent tests were made, including four in which the recipients had been sensitised not only by skin grafts but also by repeated weekly injections of donor blood Half produced no visible reaction, and none of the remainder secured a response greater than + The reactions produced by serum were probably non-specific, for they occurred equally often in the thirty-four trials in which normal guineapig serum was injected intradermally into normal recipients They differed in timing from even the weakest reactions brought about by the transfer of low doses of sensitised cells a feeble and diffuse inflammation was usually perceptible within 2–3 hours of injection and had faded by the 24th hour

The transfer of immune lymphoid cells which had been heated to 48 5° for 20 min produced no reaction greater than +

In three experiments the procedures of the direct and transfer reactions were combined 5–7 5 million sensitised regional lymph-node cells from a Heston inbred guineapig R were mixed with 8–10 million normal lymph-node cells (representing "antigen") from the corresponding donor D and the mixture was at once injected into a third guineapig belonging to the same inbred strain as R. The reaction elicited by the mixture was +++ in all three cases, D cells alone produced a reaction of +, and the sensitised R cells alone produced no reaction whatsoever Although the reactions produced by the mixture were unexpectedly weak, they were strong enough to justify the obvious supposition that the tuberculin-like inflammatory response which we have been studying is due to some local interaction between antigen and sensitised lymphoid cells

Controls for the specificity of the transfer reaction require special consideration In the preceding section it was said that only in a small minority of thirty-seven independent trials did the intradermal injection of normal lymphoid cells into normal animals produce a reaction as great as + To these may be added the five animals registered in table III, in which lymphoid cells were taken from animals which, though carrying homografts, were not yet sensitive, or only feebly sensitive, when the transfer tests were carried out These controls do not eliminate the possibility that the transfer reaction might represent some non-specific consequence of the state of sensitivity as such. Six experiments were therefore done in which highly sensitised cells from inbred (Heston) recipients were injected either into the recipient itself or into some other member of the Heston inbred strain The reactions were negative throughout In four of the six experiments the sensitised Heston cells were injected intradermally into the homologous donor, to assure ourselves of their ability to provoke a strong reaction.

It should be added that "controls" in which sensitised cells are injected into a third guineapig related neither to D nor R are fundamentally unsatisfactory in design The third guineapig must often possess antigens in common with D, and should therefore react with a violence proportional to the degree of antigenic overlap between them

DISCUSSION

At present we have no reason to question the obvious assumption that the "transfer reaction" does indeed represent a passive cellular transference of the state of sensitivity that is disclosed by the "direct reaction" In the direct reaction, an animal in a generalised state of sensitivity is confronted locally with antigenic matter, and in the transfer reaction an animal in which "antigen" is distributed throughout the body is confronted locally with sensitised lymphoid cells The difference between the two reactions is probably one of tactics and not of principle, both appear to depend upon a local interaction between antigens and sensitised lymphoid cells

The fact that the homograft reaction in guineapigs can be made to express itself as a dermal hypersensitivity of the tuberculin type, transferable by activated lymphoid cells but not by serum, adds strength to the analogy that has so often been drawn between the two The homograft reaction, in the form in which we have considered it, evidently belongs to the same general class of immunological reactions as the drug and bacterial allergies, the sensitivities produced by the injection of small quantities of antigen-antibody complex,[16] and that component of autoimmune reactions which is responsible for the lymphocytic infiltration and partial or complete destruction of the tissue against which the immunity is directed [17–18] All these reactions can be made to manifest themselves as dermal hypersensitivities of the delayed type, and in all of them—including the homograft reaction [2 3 19]—the "antibodies" behave as if they were attached to cells

The "second set" reaction that is so familiar to students of tissue transplantation—the accelerated athreptic breakdown of a second homograft on an animal which has already rejected a first—is probably a general manifestation of the phenomenon which in guineapigs and man takes the peculiar form of a dermal hypersensitivity The second-set reaction is analogous to a skin reaction in the sense that it shows up a pre-existing state of sensitivity, it can hardly depend upon a "secondary response" as the immunologist understands that term

Two other phenomena are almost certainly cognate with the direct form of the hypersensitivity reaction as we have described it in the text The first is the "recall flare" of Rapaport and Converse,[20] in which the otherwise quiet site of a rejected human homograft becomes swollen and red over the period during which a living homograft subsequently transplanted from the same donor is being rejected. The existence of this recall flare suggests that "homograft antigen" or some component of it still lingers in or around the site of a rejected homograft, and this in turn might account for the extraordinarily long persistence of the state of sensitivity produced by skin homografts and other solid homografts, when compared with the evanescent sensitivity produced by the intraperitoneal injection of dissociated cells (Billingham, Brent, Brown, and Medawar, unpublished work)

The second is the phenomenon first described by F K Sanders and since studied in detail by Darcy [21] Homografts killed by repeated freezing and thawing provoke no reaction on their own account, but become the seat of a brisk infiltration by round cells when they are implanted into rabbits which have been sensitised beforehand by living homografts from the same donor The dead homografts presumably contain some component of the sensitising antigens present in living homografts The antigen which we have used in analysing the direct reaction is, however, a "complete" antigen, in the sense that it has the power not merely to reveal a pre-existing state of sensitivity, but also to provoke it in the first place It has not yet been proved that this complete antigen is necessary to evoke the direct reaction some fraction of it may suffice

Our inability to secure the transfer reaction with "immune" serum tells against the view that the inflammatory changes which we have described are due to a reactivity of the Arthus type The peculiar violence of the transfer reaction in rabbits is nevertheless suspicious, and it is by no means impossible that, with hyperimmunised animals especially, some Arthus-like component should be present

SUMMARY

The reaction against skin homografts in guineapigs can be made to express itself as a hypersensitivity reaction of the delayed type

Two reactions are described (*a*) a "direct reaction", in which antigenic matter extracted from the tissues of a homograft donor is injected intradermally into a sensitised recipient, and (*b*) a "transfer reaction", in which cells taken from the regional lymph nodes of a sensitised recipient are injected intradermally into the homograft donor

The transfer reaction is thought to represent a passive cellular transference of the state of sensitivity revealed by the direct reaction The transfer reaction was not elicited by "immune" serum or by heat-killed lymphoid cells

The occurrence of these reactions strengthens the analogy between skin transplantation immunity and other immunological reactions that are thought to be mediated through cells

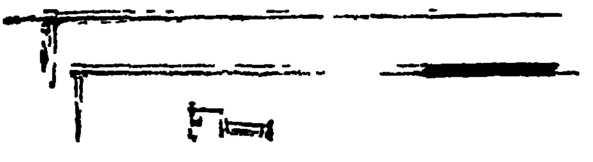
New Inventions

FLEXIBLE ŒSOPHAGOSCOPE

A few years ago the Genito-Urinary Manufacturing Company Ltd. made up for me a flexible œsophagoscope which consisted of an outer tube, the distal part being flexible, and an inner tube carrying the light and lens system, which was also flexible in its distal part

Experience has shown that this complicated and expensive flexible inner tube is not essential, and the œsophagoscope has been modified using a straight inner tube carrying the light and built-in suction and with a telescope attachment



To pass the instrument, an œsophageal tube no 30 FG (18EG 60BE) is threaded through the outer tube projecting about 8 in from the end, and this enables the œsophagoscope to be passed very easily into the œsophagus of a conscious patient who has had premedication and a local anæsthetic applied to the throat The œsophageal tube is then withdrawn and the rigid tube is inserted The telescope attachment is joined and enables an excellent view to be obtained A biopsy specimen can easily be taken using 60 cm œsophageal biopsy forceps

The apparatus is supplied by the Genito-Urinary Manufacturing Company, Ltd , of 28A, Devonshire Street, London, W 1

Reviews of Books

Orthopædic Disorders

Ernest Aegerter, M D , professor of pathology and director of the department of pathology, Temple University Medical Centre and School of Medicine, professor of orthopædic pathology, Philadelphia General Hospital, J A Kirkpatrick, Jr , M.D , radiologist, St Christopher's Hospital for Children and Children's Heart Hospital, assistant professor of radiology, Temple University Medical Centre Philadelphia and London W B Saunders 1958 Pp 602 87*s* 6*d*

This is one of the most original and praiseworthy orthopædic textbooks that has appeared in recent years It has been written, not by a surgeon, but jointly by a pathologist and a radiologist Together they have reviewed all the common (and many of the rare) diseases of the skeleton In the case of each they have tried to show just how the pathological changes produce the typical clinical features, and how they give rise to radiographic signs

The main body of the book is prefaced by half a dozen brief chapters on the normal histogenesis of bone and connective tissue For the sections that follow, the literature has obviously been painstakingly surveyed and abstracted In consequence even a very experienced surgeon, looking up a condition with which he is familiar, is likely to discover facts previously unknown to him Yet this is not a "heavy" volume, abounding in paragraphs of small print and lengthy footnotes What distinguishes this work is that, though its scope is wider than the modest title suggests, it is written throughout in a lucid, consistent, and elegant style

The Interference Microscope in Biological Research

A J Hale, M B , CH B , PH D , lecturer in physiology, University of Glasgow Edinburgh E & S Livingstone 1958 Pp 114 20s

The phase-contrast microscope is now widely used for studying transparent specimens such as living cells The interference microscope is newer and less familiar The images it produces are free from certain defects inherent in phase contrast, but its most important advantage is that it can be used to make quantitative measurements of optical-path difference This quantity can be related to the dry mass per unit area of a cell, so that it is now possible to "weigh" parts of cells In this book the more important instruments and the basic theory underlying their use are described It should prove useful to biological and medical workers, but its value to the uninitiated might have been increased if more indication of the types of problem which can be investigated had been given

Collected Papers

Through Pædiatrics to Psychoanalysis D W Winnicott, F R C P London Tavistock Publications 1958 Pp 350 35*s*

In accordance with the established practice of psychoanalysts, Dr Winnicott has assembled under one cover the articles he has written in various journals They extend over a period of twenty-one years and are preceded by two chapters, on anxiety and fidgetiness, from an earlier book of his on disorders of childhood Dr Winnicott's entry into the field of pædiatrics and the beginning of his personal psychoanalysis occurred in the same year, three years after he qualified Since then he has become more and more occupied with the psychoanalytical aspects of children's illnesses, and has shown himself to have a strong sense of mission This is well illustrated in the last contribution in the book—an address to the Eighth International Congress of Pædiatrics—in which he urges that all pædiatricians who wish to treat the psychological troubles of children must take a psychoanalytical training Dr Winnicott is one of the leading British psychoanalysts, his innovations in theory have attracted much attention and he has developed a notable skill in conveying his views to large sections of the public It is therefore to be regretted that, as the bibliography of this book shows, he has disregarded almost entirely the invaluable contributions to child psychology and psychiatry made by non-psychoanalysts This concentration of interest, however, enables him to present effectively his experience and views

THE LANCET

LONDON 13 SEPTEMBER 1958

The Report on Prisons

THE latest report on prisons[1] is disquieting yet in some ways encouraging. It is disquieting mainly in its revelation of still more overcrowding: the increase in prison population seems likely to engulf the institutions now in preparation and preclude the improvement expected from them. Between 1952 and 1956 the average number in prisons and borstals dropped from 22,558 to 19,776, but in the early months of this year it was, at 24,700, the highest yet recorded.

One of the notable facts given in the report is that last year the prisons received no fewer than 39,000 men who had not been sentenced. The practice of remanding in custody sometimes seems haphazard, and this high figure strengthens the suspicion that it is often unnecessary. When specialist reports on a prisoner are needed they can often be obtained as easily while he is on bail. Some magistrates seem to remand a man in prison whom they have no intention of sentencing, "to give him a taste of it"; indeed the report mentions that 38–40% of the men imprisoned before trial are not imprisoned after it. This policy may appeal to some, but it must also tend to bring justice into disrepute. Of the men actually under sentence the majority (68%) were in prison for six months or less, while for women the figure was 85%. Perhaps this short-term population could be reduced by wider use of probation (though that excellent service must already be stretched to very near its limit), or by the introduction of the suspended sentence, of which Dr SCHMIDEBERG recently spoke so enthusiastically from American experience[2], or, indeed, by increasing the use of our own conditional discharges. For the people sent to prison for a long time, parole gives an excellent incentive and could be used much more widely, as the "Bristol experiment" (placement of prisoners in hostels) has shown.

Among the reasons for imprisonment we note 5539 receptions for non-payment of fine: in 49% of cases the prisoner had *not* (report's italics) been allowed time to pay. Though the use of statistics in penology is full of hazards[3] it is at least worth mentioning that the increase in crimes of violence against the person, which has been greeted with such clamour, is in fact proportionate to the total increase (about a ninth since 1954), except in the 15–21 age-group. Sexual offences, however, show a larger increase in these imprisonment figures (of about a third), larceny remained static and fraud actually decreased. The rise in crime has hit the borstals particularly hard, and the report says that boys have waited for up to six weeks in local prisons for a place in a reception centre. But these are not the only young people in prisons: we read with some horror that 370 boys and girls between 14 and 17 were remanded there; and 1 boy aged 15, and 8 aged 16, were actually sentenced to terms of imprisonment—under the Criminal Justice Act of 1948, section 17(1).

Looking to the report for encouragement, we read of a modest increase in psychiatric services and of successes in a group-psychotherapy unit. Of great interest, too, is the related success of the "Norwich experiment", which comprises the regular evening "association" of large numbers of men with very few officers present. A group atmosphere seems to have been created, and, to quote a governor's report, "the few anti-social and intractable types were contained by this atmosphere, confirming the impression that so far as possible each group must learn to live with and tolerate all types." This remarkable governor also writes of the "identification of officers with individual inmates" which results, and of the value of such personal relationships. This is but one of a series of extracts from the annual reports of senior staff which, in appendix 1, make perhaps the most interesting reading. A new wind really does seem to be blowing through our ancient gaols, and even experienced prisoners are known to admit that things have changed for the better over the last couple of years. Recruitment of the right type of prison officer is extremely important, and the report says little about this, although it is perhaps reassuring to read that, of men approaching the authorities, only 1 in 35 is appointed, of women inquirers, 1 in 63 is chosen.

The commissioners cannot be expected, perhaps, to suggest reforms in such a volume as this, but in our view the essence of progress must be to transform the prison into a truly "therapeutic community". This endeavour will have much in common with what many mental hospitals are trying to do, and the two spheres should become more aware of each other. Such projects would draw much from the wider aspects of Dr. MAXWELL JONES' very interesting work at Belmont, and from Dr CEDRIC SIMPSON's unit at Wormwood Scrubs. Though the running of a whole prison on something approaching these lines is still a long way off, some enlightened administrations are finding their way there gradually, and they must be watched and encouraged. It really is time that the commissioners and the trade-unions came to some better understanding about contract work in prisons. Too little is done towards rehabilitation, and too many men moulder away doing nothing useful or constructive. The day is long past when we should be content to regard such misery and waste as a proper part of punishment: if the inmates of a Russian prison[4] can earn reasonable wages, which are paid to dependants, why should not ours have an equal chance of regaining usefulness and self-respect? The Russian attitude towards non-political crime is liberal, and in their prisons the internal discipline is said to be handled by a panel of prisoners who sit in judgment on their fellows. This form of group technique has not been tried here yet, though the commissioners report a "working party" of prisoners and very senior officers which discussed round a table problems of prison administration—*an event said to be without precedent*

The fact that deficiencies in the prison service are as bad as they are, that research is so scanty, and that progress is so slow does not necessarily put the commissioners under a cloud They are but doing the best *with what they have, and if they have little it is we,* the public, that are to blame This branch of therapeutics, though very important to our society, is given low priority.

Sphincter and Hiatus

UNTIL quite recently our great protector that lies between the stomach and the gullet might well have been called the Sphinx—even the Sphinx of Sphinxes—because its behaviour seemed so enigmatic The name is more apt than it may seem, for the Sphinx of Thebes was not only a riddler but also a *sphincter* or strangler (of those who could not solve her riddles) Today the riddles of the cardiac or œsophageal sphinx are happily being solved Apart from the personal experience of each one of us that, as a rule, there is some effective check to the reflux of stomach contents into the œsophagus, we now feel more sure, from the work of FYKE et al,[1] ATKINSON et al,[2] and CREAMER and PIERCE,[3] among others, that there really is a sphincter around the lower end of the gullet, even though it has not yet been displayed by dissection There seems to be a band of higher muscular tension around the lower 2–3 cm of the œsophagus which resists the pressure gradient between abdomen and thorax It relaxes as the cup is raised to the lips in drinking, and so allows fast-moving liquid to pass through before the peristaltic wave arrives at the cardia and peters out there It also relaxes at an early stage in the simpler act of swallowing These physiological features are thought by CREAMER and PIERCE [3] to explain why certain careful investigators in the past have failed to identify the sphincter

Normally this zone of higher muscular tension lies partly in the abdomen, below the diaphragmatic hiatus (As a recording tube is withdrawn from the stomach, the position of the hiatus is indicated by a fall in pressure and by a simultaneous inversion of the respiratory waves in the tracing) Being thus in contact with the abdominal pressure, the sphincter responds when this increases As in a bucket of fluid, pressure in the abdomen is greatest at the lowest point (CANNON,[4] FYKE et al [1]), and even tilting of the body by 15° will raise the pressure around the intra-abdominal portion of the cardiac sphincter, perhaps also evoking protective contraction In people with hiatus hernia the abdominal pressures are carried into the intrathoracic part of the stomach above this, in a proportion of cases, one can detect a sphincteric zone in which pressure is increased, and above this again there is the sudden drop and inversion signifying a thoracic pattern Sometimes the sphincteric zone shows little or no increase in tension, and in these cases acid reflux readily occurs ATKINSON et al [2] have found good correlation between the clinical evidence of reflux and the graphic evidence that the sphincter is poorly developed If this finding is fully substantiated by further experience, it will explain why hiatus hernia presents in so many different ways—particularly as regards the presence or absence of acid reflux—and why patients may have reflux though they have no hernia at all The evidence of pressure tracings is the more valuable because in some cases the presence of a hiatus hernia is not revealed by radiography Moreover, pressure tracings and cinefluoroscopy in patients with hiatus hernia have also *shown* (CROSS et al [5]) *abnormal* muscular behaviour in other parts of the gullet, particularly muscular overaction in the lower part, together with underaction in the upper part Correlation of these with dysphagia will sometimes provide a satisfactory explanation for this symptom, in cases of œsophagitis, ulcer, or stricture *In the same way,* OLSEN and CREAMER [6] have elucidated the distinction between achalasia and diffuse spasm

Despite the doubts raised so cogently by Dr HOUGHTON in his letter last week,[7] we shall be surprised if the pressure tracing does not turn out to be an important means of investigating patients with hiatus hernia and other disorders of the gullet Even with a large hernia, a good sphincter (if such exists) should prevent reflux and so render surgical repair unnecessary, provided other symptoms such as pain and eructation are not serious Where there is reflux and the sphincter is poor or absent, it may at first sight seem useless to repair the hernia, for the sphincter will still be weak But if the sphincter is moved to below the diaphragm, it may be reinforced by the abdominal pressure—which explains why some cases of reflux are cured by simple surgical repair (BOTHA's [8] conception of the rosette of mucosal folds rendered active or erect by the *muscularis, as check against reflux,* is complementary, not alternative to nor exclusive of the idea of the sphincter) Mere tightening of the hiatus, even with creation of an acute angle between the lower end of the gullet and the fundus of the stomach, is of more doubtful value against reflux Again, in patients whose symptoms—particularly acid reflux—recur after surgical repair, the pressure tracing may prove to be of great value If, in a patient with troublesome reflux, the repair is found to be intact but the sphincter poor or absent, a difficult situation will be evident Perhaps some drastic measure to diminish gastric acidity, will be required, perhaps a surgical attempt should be made to fashion a check against reflux, which will nevertheless allow vomiting when necessary, or perhaps the jejunal segment of MERENDINO and DILLARD,[9] interposed to act as a physiological sphincter, may be the answer

Obviously the subject is very far from being exhausted Apart from the necessity for substantial verification of the above findings, many questions may be asked For example, why should some patients, whether they have a hiatus hernia or not, have a competent intrinsic sphincter, and others none? May there be some drug which could restore tone to a lost sphincter, or in reverse could relax the action of one that is too energetic? All in all, it seems that the riddling function of this sphinx remains, particularly when her strangling powers have been lost

Excision or Resection for Rectal Cancer?

DOES preservation of anal function sometimes jeopardise cure after operation for rectal carcinoma? MAYO et al[1] have compared survivals after anterior resection and abdominoperineal excision, and have found, surprisingly, that 60% of 476 patients traced after anterior resection had survived for five years, compared with 52% of 580 traced after excision It might be suspected that there was bias against excision by the inclusion in the second group of many late cases, but almost exactly half the resection group had metastases (231 cases with, 245 without) compared with rather less than half in the excision group (273 with, 307 without), so the bias, if any, lay against "conservative" resection What then of level?—for surely excision must be a more effective means of cancer clearance when the growth and its metastases lie below the peritoneal reflection? Again surprisingly, the five-year-survival statistics favour resection, not only in the absence but also in the presence of lymph-node involvement, when the lesion was situated in the zone 6-14 cm from the dentate line 2 inches is the agreed minimal length distal to the growth for adequate mural clearance, and conservative resection cannot be performed for growths lower than this It is only fair to observe that the resection group consisted of patients who had been operated on with the hope of cure, and did not include patients who had been operated on with the aim of palliation, whereas there is no evidence that there was such a distinction in the abdominoperineal group

GOLIGHER,[2] though in favour of anterior resection for growths at the rectosigmoid or intraperitoneal part of the rectum, will not countenance its routine use, with the aim of cure, for tumours at a lower level This, in fact, represents the current British view MORGAN[3] has observed that the crude survival-rate of 66% after 110 radical anterior resections for lesions of the intraperitoneal rectum and rectosigmoid, when corrected (81%), is little different from the corrected survival-rate for a comparable group submitted to combined excision (78%) With so little difference as regards survival it is proper to select the operation which is less disabling, and it must be borne in mind that a colostomy is not the only disadvantage of excision—impotence is a sequel in a quarter of the men[4] The experience of BUTLER[5] and of MUIR[6] is similar All agree that resection is the operation of choice for lesions in the upper third That the operation is valuable at lower levels (6-14 cm from the dentate line) for palliative purposes when hepatic metastases are present is not denied, and a case can be made out for its use at this lower level for the aged in all circumstances,[7] since colostomy management is fraught with difficulty in the elderly, who so often live in lonely squalor many rectal growths are slow to develop, and even imperfect eradication may serve the allotted span of an old patient, and the operative risk of resection is lower than that of excision in the elderly Otherwise there are no British advocates of resection as an elective curative procedure at this lower level

Yet the Mayo Clinic is not alone in its reports of favourable results of resection for lesions below the peritoneal cul-de-sac BEST and RASMUSSEN[8] regard it as appropriate for three-quarters of patients with lesions 5-12 cm from the anal margin, and find that survival is comparable to that after excision Furthermore they observe that, whereas excision in their hands is followed by impotence in 75% of cases, after resection the figure is only 25% Nevertheless it is difficult to understand why resection should be as effective as a wider excision in an area where lymphatic spread is known to occur laterally as well as proximally, unless perhaps our conception of the pathological progression is wrong HERMON TAYLOR[9] takes the view that blood-stream spread is the most important factor in prognosis, and that when it occurs it has usually done so before the institution of treatment—thus rendering extensive lymphatic dissection useless This may be so, but it has yet to be demonstrated, though venous invasion has been shown in as many as 50% of specimens[10] As a result of the controversy which has continued throughout the post-war decade, resection is now established as the operation of choice for lesions of the upper third of the rectum In the next decade controversy is likely to centre on the surgical treatment of lesions of the middle third

Contraceptives

THE doctor seeking reliable information on contraceptives has no official source to turn to on this subject the *British Pharmacopœia* is silent Yet the need for informed guidance is great, for some manufacturers may be tempted to make excessive claims, and these are not readily disproved Accordingly the Family Planning Association does a notable public service by publishing its *Approved List of Contraceptives* The contraceptive substances listed must comply with the Association's requirements about quality, efficiency, and harmlessness, and standard of presentation The list, besides being an indispensable source of information for doctors, pharmacists, and nurses, acts as a stimulus to manufacturers to develop effective contraceptives and to present them soberly The latest edition[11] includes an explanation of the purpose of the list and the criteria for approval

JOURNEY INTO SPACE

PROGRESS in the exploration of space is rapid. This year we have seen the establishment of satellites in orbital flight around the Earth, and the safe return of two dogs from a height of 279 miles. It seems likely that a multi-stage rocket may soon make the 250,000-mile journey to the Moon.

To place an object in orbit around the Earth, velocities of 18,000 m.p.h. are needed, and to carry an object out of the Earth's gravitational field the velocity of escape must be about 25,000 m.p.h. Rockets, powered conventionally, can attain such speeds only by using large amounts of fuel. The American Vanguard, for instance, needs 1000 lb. of rocket and fuel for every 1 lb. of pay-load. This expensive ratio of propellant-weight to vehicle-weight is at present the most serious impediment to manned space flights. Development of new rocket fuels, possibly nuclear, would render much more feasible a vehicle heavy enough to contain a man with his necessary equipment and yet with power to bring him safely back. At the present rate of progress such a vehicle may be designed within the next few years.

It is reasonable to suppose that man's first journeys into space will be in an Earth satellite, and this will long precede any attempt at inter-planetary travel. Whether man can in fact orbit around the Earth is the first problem which "space medicine" seeks to answer. Space medicine is the youngest of the medical sciences. Fathered by physiology and nurtured by aviation medicine, it has now freed itself of the taint of miscegenation with science fiction. Some aspects of its scope are dealt with in a symposium published in the July issue of the *Journal of Aviation Medicine*.

Conventional powered flight has taken man well above the respirable portion of the Earth's atmosphere, which extends a mere 5 miles. Survival in the tenuous air of the outer atmosphere depends on pressurisation and the maintenance of a high concentration of oxygen. Brief sorties beyond the atmosphere involve no new respiratory problems, except the provision of safety measures if pressurisation should fail or emergency "bail-out" prove necessary. The atmosphere, however, has functions other than the provision of oxygen under pressure. The relatively constant temperature of the Earth depends on its atmospheric shell, the atmosphere also acts as a shield against cosmic and auroral radiation and the assaults of meteors. Man, beyond the atmosphere, will be exposed to extremes of temperature, a yet unknown amount of radiation, and the possibility of collision with meteoric bodies. The intensity and penetrance of the radiations will be of crucial importance in determining the possible duration of exposure of man to these fields.[1] The equipment necessary for protection, for the provision of oxygen, and for pressurisation will impose a weight penalty intolerable with present methods of propulsion.

If space travel is to become a reality, thought must be given to the provision of food and water within acceptable weight limits. On Earth there is a natural cycle for the conservation and re-utilisation of the materials necessary for life. This cycle, involving the passage of individual elements through animals, plants, and bacteria, takes a long time but is complete and self-perpetuating. To economise in weight, some form of closed ecological system for the re-utilisation of all the body wastes must be developed. Clark[2] says "this task of developing an adequate closed food cycle is the most difficult and, hence, the most significant task that must be completed before man can begin extended space voyages". The value of such research is not restricted to space travel. In many circumstances on the Earth and oceans the chances of survival could be increased by artificial systems for recycling human wastes.

The fundamental work on these problems can be undertaken in the laboratory, but the problems associated with increased and decreased gravity are less amenable to a ground experimental approach. During the high-speed take-offs necessary to reach orbiting and free heights, the acceleration forces will impose on the space traveller weights 4-8 times that of gravity. These stresses can be readily simulated on the ground by the human centrifuge, and there is little doubt that, exerted for short periods, they are tolerable: much depends on the position of the person and the clothing worn. On the other hand, the lack of gravity or "weightlessness" which will develop when the space craft becomes a celestial body floating freely in the Earth's gravitational field is far less easily investigated. Gerathewohl and Stallings[3] have succeeded in producing "weightlessness" or zero gravity for short periods by flying an aircraft in parabolic arcs at altitudes of 17,000-25,000 feet. They found that, as predicted, there were disturbances in the otolith organs, which were manifested by ocular illusion. With further investigation it may be found that the psychological and physiological effects of "weightlessness" are intolerable. If this is so it may be possible to provide the space vehicle with some artificial device for producing the sensation of gravity.

HYDATID DISEASE

THE dog is the optimum definitive host of the tapeworm *Echinococcus granulosus*, while the domestic and wild ruminants, and ungulates such as the ox, pig, deer, and *particularly the sheep, are intermediate hosts for the* larval stage or hydatid, which develops in the lungs or liver after the ingestion of ova from an echinococcus-infested carnivore. Man may also ingest the ova, and human hydatidosis has been heavily endemic in certain areas of the world, such as Iceland, New Zealand, Southern Australia, and parts of South America, where an intimate sheep-dog-man relationship prevails. It is not without reason that human hydatidosis has been termed *la maladie des mains sales*.

A long-recognised public-health measure to avert human hydatid disease is to prevent dogs being infected with the tapeworm, and this involves ensuring that the infected viscera of slaughtered animals are destroyed. Dramatic results have been achieved in Iceland and Australia by vigorous promulgation of this policy. Another measure—the regular administration of anthelminthic drugs to every dog—has helped to diminish the regional canine reservoirs of echinococcus.

In Britain hydatidosis in man and domestic animals is relatively rare, the incidence in sheep and in man is highest in South Wales. It is important that this relative freedom from hydatidosis be preserved, and we are therefore disturbed to learn that New Zealand ox livers, containing hydatid cysts have been imported into this country, presumably for pharmaceutical purposes or animal feeding, as many as 3000 bags of livers have been imported in one week, and apparently up to 20% have been infected Even more disturbing is the report[1] that many livers were being disposed of to retail butchers without mention of their diseased condition, it is obvious that small cysts embedded within the liver substance would not readily be detected

---

[1] Schaefer, H. J. *J. Aviation Med.* 1958, 29, 492.

[2] Clark, C. C. *ibid.* p. 535.

[3] Gerathewohl, S. J., Stallings, H. D. *ibid.* p. 504.

There seems to be no statutory bar to the importation or sale of these infected livers, provided they are not intended for human consumption, but the Ministry of Health, if satisfied that there is an urgent need in this country for pharmaceutical products manufactured from animal livers, might consider whether it would not be best to insist that the livers be processed in their country of origin An even more serious gap in public-health law is that there is nothing to prevent a retail butcher exhibiting for sale as pet food meat scraps and organs unfit for human consumption, on the same stall as normal sound meat This undesirable practice seems to be growing, and there is urgent need for legislation to make it an offence

ABNORMAL BETA-GLOBULINS

DEVELOPMENTS in the research on abnormal human hæmoglobins in man have been followed by the demonstration of similar polymorphism for other proteins It was known that cow's milk contained two β-lactoglobulins, but this observation had usually been made on pooled milk When samples from individual animals were examined it was found that the two lactoglobulins were distributed as polymorphic characters, some cows producing only one of the two globulins and others both—representing homozygous and heterozygous phenotypes [2 3] In the plasma of man there are two haptoglobins [4]—α_2-globulins capable of binding free hæmoglobin [5]—which also are distributed as if they are determined by allelic genes Smithies [6 7] also found in human plasma three different β-globulins which he called β-B, β-C, and β-D There is evidence that the formation of these three β-globulins is genetically controlled, and Smithies suggests that each may be determined by one of three allelic genes He observed the patterns C, BC, and CD C was most commonly found in the Canadians he investigated, but C plus B occurred in 1% of Canadians and C plus D in about 4% of American Negroes The phenotype CD was even commoner in Australian aboriginals, in whom one example of a fourth phenotype (D) was discovered [8] The phenotypes B and BD, which are also possible, have so far not been described

Harris et al [9] working in Britain, have studied the β-globulins of man by means of the discontinuous buffer system of Poulik [10] In a series of 153 Africans from the Gambia they found four examples of CD Two types of D β-globulin were identified which differed slightly but distinctly from one another in their electrophoretic behaviour, these have been named D_1 and D_2 In 139 English people no examples of the CD_1 or the CD_2 phenotype were found, but the combination B plus C was found in two people The two B β-globulins were not identical, so there seem to exist a B_1 and a B_2 The family of the person with the B_1C phenotype was further investigated, and a pedigree was constructed which showed that the β-globulin B_1 is genetically determined, and that the members of the family with the B_1C phenotype are heterozygous for the appropriate gene.

Obviously the human serum β-globulins deserve to be studied with the close attention that has been given to the hæmoglobins, they are likely to be of equal interest to the biochemist, the geneticist, and the anthropologist Polymorphism is the outcome of the selective advantages and disadvantages in a particular environment of inherited characters which are determined by allelic genes and which are neither dominant nor recessive in the phenotype In the case of the hæmoglobins much interest has been taken in the resistance of carriers of the trait for sickle-cell hæmoglobin against the lethal effect of malignant malaria It will be of special interest to see which selective advantages the various β-globulins confer against diseases due to infection, climatic influences, and malnutrition. A polymorphism for serum-β-globulins has also been demonstrated in cattle,[11 12] in which there are three different proteins determined by a three allele system resulting in six phenotypes In cattle the geographical distribution of one of the β-globulins suggests that it is associated with tolerance of the more severe northern climates

THE "MEDICAL OFFICER"

As an independent journal "for medical men and women in the Government and municipal services"—a group which, though influential, is not large—the *Medical Officer* has attained its golden jubilee [13] only because it has always been so well worth reading The difficulties of producing a weekly journal for a small group are very real, and this is the only public-health weekly in the world, but the benefit to readers is real too, for a periodical which comes out once a week can "combine some of the liveliness and topicality of a newspaper with the more sober and lasting qualities of a scientific journal." The particular attractiveness and value of the *Medical Officer* derives largely from the Elliston family, its hereditary editors George Elliston, son of a physician in Ipswich and nephew of the first M O H for that town, was on the staff of Sir Joseph Causton & Sons, the printers, when he founded the journal in 1908, and later, as secretary of the Society of Medical Officers of Health, member of Parliament, chairman of the health committee of the City of London, chairman of the board of management of the London School of Hygiene, and in many other ways a power in public health, he was a remarkably well-informed as well as a naturally able editor—with what his old friend Sir Allen Daley describes as "the journalistic 'nose' for finding out any unusual development and the barrister's flair for pungent exposition" Since Sir George Elliston's death in 1954, his eldest son, Mr Lewis Elliston, who had long been working with him, has carried on the journal with the same mixture of perception, friendliness, and zest We wish it many more years of its valuable service to medicine

THE COST OF ORAL IRON PREPARATIONS IN FAMILY AND IN HOSPITAL PRACTICE

SIR STANLEY DAVIDSON
B A Cantab, M D Edin, F R C P E, F R C P
PROFESSOR OF MEDICINE IN THE UNIVERSITY OF EDINBURGH

JOHN RICHMOND
M B Edin, M R C P E, M R C P
LECTURER IN THE DEPARTMENT OF MEDICINE OF THE UNIVERSITY

TWENTY years ago Davidson and Fullerton (1938) clearly established that, for correcting iron-deficiency anæmia, ferrous sulphate was as effective as any of the iron preparations then available (ferrous carbonate, ferrous chloride, colloidal iron, iron and ammonium citrate) and had a considerable advantage in cost During the past ten years a number of organic preparations of iron have appeared on the market and gained wide popularity Further studies have therefore been undertaken to ascertain which oral preparation is the most suitable in regard to therapeutic efficiency, incidence of toxic effects, and cost

A therapeutic trial by O'Sullivan, Higgins, and Wilkinson (1955) showed that when ferrous sulphate, ferrous gluconate, or ferrous succinate was given in doses containing equivalent amounts of elemental iron (210 mg daily), each caused a similar rise in the hæmoglobin level

Kerr and Davidson (1958a and b) have recently reported the results of two controlled investigations In the first, ferrous sulphate, ferrous gluconate, ferrous gluconate plus vitamin C, and control tablets containing lactose were administered to groups of women in the last trimester of pregnancy The amount of elemental iron given daily in each preparation was 105 mg The mean rise in the hæmoglobin level in the three groups receiving the iron-containing tablets was approximately similar, and there was no difference in the incidence of gastrointestinal "side-effects" between these three groups or between the treatment groups and the control group In a second trial ferrous sulphate, ferrous gluconate, ferrous succinate, ferrous calcium citrate, and control tablets containing lactose were administered in turn to groups of nurses With the dosage of iron given, none of the iron-containing preparations caused more side-effects than the control tablets By using known and unknown control tablets it was established that the symptoms complained of by the nurses were mainly psychological in origin

Both in family and in hospital practice, iron-deficiency anæmia is one of the diseases most commonly encountered, and very large amounts of iron are prescribed annually for its treatment The choice of oral iron preparation is determined partly by the doctor's own clinical experience and partly by the pressure of advertising. Since ferrous sulphate, ferrous gluconate, and ferrous succinate, when given in tablets containing equivalent amounts of elemental iron, have similar therapeutic efficiency and similar toxicity, the problem of their relative cost assumes great importance This is particularly the case today when there is an urgent need for economy in the National Health Service

Accordingly, we have inquired into the comparative costs of the widely used non-proprietary and proprietary iron tablets, and the frequency with which they are prescribed

Comparative Cost of Various Iron Tablets

Information about the cost of the more popular iron tablets in present use in family practice is summarised in table I The four proprietary preparations are designated "proprietary 1, 2, 3, and 4"

Column A shows the basic price of 100 tablets Because of the system of costing, the allowance which the chemist receives from the Government for the purchase price of a drug used in dispensing N H S prescriptions is not always the same as the net cost Hence the former figure has been given The prices of non-proprietary preparations have been obtained from the National Health Service, Scotland, Drug Tariff (January, 1958) and Amendments (to April, 1958), and those of proprietary preparations from The Retail Chemist Trade Price List of Proprietary Articles (1957) and Supplements (to March, 1958), the latter prices being adjusted to accord with the Drug Tariff system of payment

Most iron preparations are cheaper to the chemist if purchased in bulk For proprietary preparations deduction is made if the chemist endorses the prescription to the effect that he has dispensed the 100 tablets from a larger pack Throughout the table, therefore, the reduced cost of 100 tablets of the proprietary preparations if dispensed from a 1000 pack is shown in parentheses For non-proprietary preparations, however, the figure shown in column A is always paid, regardless of the size of pack In some circumstances the proprietary preparations are subject to 30% purchase-tax Purchase-tax has not been included in the prices given in column A, but where applicable has been listed separately in column B

Column C gives the total amounts which the chemist receives for dispensing 100 tablets on an N H S (Scotland) prescription These figures (to the nearest halfpenny) have been derived as follows

Net cost of 100 tablets (column A) plus oncost allowance (25% of net cost), plus 1*s* 7*d* dispensing fee, plus 1$\frac{9}{10}$*d* container allowance, plus refund of purchase-tax if applicable

The cost to the N H S in Scotland of a prescription for 100 tablets of each of the iron preparations is shown in column D This amount is the figure given in column C minus 1*s* (the prescription charge paid directly to the chemist by the patient)

The prices to patients of 100 iron tablets if purchased at a chemist's shop without a prescription are listed in column E

TABLE I—COMPARATIVE COST OF 100 TABLETS OF DIFFERENT ORAL IRON PREPARATIONS

Oral iron preparation	A Basic price of 100 tablets of different oral iron preparations	B Purchase tax on 100 tablets	C Allowance to Chemist for dispensing 100 tablets on N H S prescription	D Cost to N H S of prescription for 100 tablets (column C minus 1*s*)	F Cost to patient of 100 tablets if purchased at chemist's shop without a prescription
Ferrous sulphate					
Ferrous sulphate tablets *B P*	1*s* 3½*d*		3*s* 4½*d*	2*s* 4½*d*	2*s* to 3*s*

Figures in parentheses denote reduced cost of 100 tablets if dispensed from a 1000 tablet pack

TABLE II—SURVEY OF NATIONAL HEALTH SERVICE PRESCRIPTIONS DISPENSED IN SCOTLAND DURING MAY, 1957

Total number of N H S prescriptions dispensed=1,689,505

Number of prescriptions in sample studied=10,495 (0 6% of total)

Number of prescriptions for oral iron preparations in sample =230 (2 19% of sample)

Number of prescriptions for different oral iron preparations and number of tablets prescribed

Oral iron preparation	No of prescriptions	Total no of tablets prescribed	Average no of tablets per prescription
Ferrous sulphate			
Ferrous-sulphate tablets *B.P*	23 (*10%*)	2268	98 6
Ferrous-sulphate compound tablets *B P C*	14 (*6%*)	1466	104 7
Proprietary 1	17 (*7%*)	1550	91 2
Total	54 (*23%*)	5284	
Ferrous gluconate			
Ferrous-gluconate tablets *B.P C*	39 (*17%*)	3176	81 4
Proprietary 2	61 (*27%*)	5196	85 2
Proprietary 3	14 (*6%*)	1068	76 3
Total	114 (*50%*)	9440	
Ferrous succinate			
Proprietary 4	62 (*27%*)	5732	92·5

Total number of iron tablets prescribed in sample=20,456

Average number of tablets per prescription in sample=88 9

Ratio of prescriptions for ferrous sulphate to prescriptions for ferrous gluconate plus ferrous succinate=1 (23%) 3 (77%)

Ratio of prescriptions for non-proprietary preparations to prescriptions for proprietary preparations=1 (33%) 2 (67%)

For proprietary preparations the retail price is fixed by the manufacturers For non-proprietary preparations the figures given represent the average prices charged by several chemists in Edinburgh at whose shops inquiry was made

This table shows that the cost to the Government of a prescription for 100 ferrous-sulphate tablets ranges from 1*s* 2*d* to 2*s* 4½*d* For ferrous gluconate the range is 3*s* 9*d* to 5*s* 7*d* and for ferrous succinate it is 4*s* 6*d* to 5*s* 7*d* If a patient purchases 100 iron tablets at a chemist's shop without a prescription the price charged will vary from 1*s* 3*d* for "Ferrous sulphate compound tablets *B P C*" to 7*s* 4*d* for one of the proprietary preparations of ferrous gluconate The cost to a patient of 100 iron tablets dispensed on a "private" prescription varies from chemist to chemist, but is usually more than the cost of the same preparation purchased over the counter or supplied on a N H S prescription

The difference in cost of oral iron preparations to the hospitals is still more striking Since most preparations are supplied to hospitals by manufacturers under contracts which are confidential, the full range of prices cannot be quoted Furthermore, the expenditure on iron tablets may be greatly reduced if very large quantities are purchased Hence the cost of iron tablets is relatively less in a large hospital which caters particularly for acute medical, surgical, and obstetric cases than in a small hospital which caters for the chronic sick We are satisfied, however, from information received from hospitals and manufacturers that the price to hospitals of proprietary and non-proprietary preparations of ferrous sulphate is only 3*d* to 4*d* per 100 tablets, whereas ferrous gluconate costs at least three to six times as much and ferrous succinate six to ten times as much

Frequency with which Different Iron Tablets are Prescribed

Family Practice

In a survey undertaken by the Department of Health for Scotland of 10,495 N H S prescriptions dispensed by representative chemists throughout Scotland during the month of May, 1957, it was found that 2 19% (230) of the prescriptions were for iron tablets This is in agreement with the observation of Dunlop, Inch, and Paul (1953) that about 3% of their large sample of prescriptions dispensed in Scotland during October, 1951, were for iron—a figure which included mixtures and injections as well as tablets Table II shows the frequency with which different preparations were prescribed and the average number of tablets ordered The terms "proprietary 1, 2, 3 and 4" refer to the same preparations as in table I

Only 23% of the prescriptions dispensed in family practice were for ferrous sulphate The remainder were for ferrous gluconate (50%) and ferrous succinate (27%) Two-thirds of the prescriptions were for proprietary preparations of iron ferrous sulphate (proprietary 1) 7%, ferrous gluconate (proprietary 2 and 3) 33%, and ferrous succinate (proprietary 4) 27%

During the month under consideration (May, 1957) 1,689,505 N H S prescriptions were dispensed in Scotland Although the sample studied represented only 0 6% of these, it probably gives a fair indication of the pattern of prescribing, since the prescriptions were obtained by random sampling If this is so, the total number of N H S prescriptions for oral iron tablets for family practice in Scotland in a typical month will be about 38,000 $\left(\frac{203\times 100}{0\ 6}\right)$, and, since the average number of tablets ordered per prescription is about 90, the total number of iron tablets dispensed per month is between 3 and $3^{1}/_{2}$ million

Hospital Practice

The number of hospital beds in Scotland is 65,802 (May, 1958), of which 22,036 are in mental hospitals A questionnaire was sent to ten general hospitals in different parts of Scotland, and (because a large proportion of beds are for mental patients whose iron requirement was thought likely to be low) to four large mental hospitals Information was requested regarding the quantities of ferrous-sulphate, ferrous-gluconate, and ferrous-succinate tablets, both proprietary and non-proprietary, used in a recent twelve-month period The replies are summarised in table III There was considerable variation in the prescribing habits in the different hospitals, but, taking them as a whole, ferrous gluconate seems to be used

TABLE III—SURVEY OF THE USE OF IRON TABLETS IN A RECENT 12-MONTH PERIOD IN REPRESENTATIVE HOSPITALS IN SCOTLAND

—	No of beds in Scotland	No of beds surveyed	% of total no of beds	No of iron tablets used annually			Total
				Ferrous sulphate	Ferrous gluconate	Ferrous succinate	
General hospitals	43,766	8,010	18 3	810,000*	815,000	135,000	1,760,000
Mental hospitals	22,036	4,063	18·4	44,000	37,000	1000	82,000
Total	65,802	12,073	18 3	854 000 (*46%*)	852,000 (*46%*)	136,000 (*8%*)	1,842,000

* The figures for numbers of iron tablets are to the nearest thousand.

almost as often as ferrous sulphate, and, although ferrous succinate has not gained wide popularity, large quantities of it are also being prescribed

If the hospitals which cooperated in the survey are typical of the remainder, the total number of iron tablets consumed annually by hospital patients in Scotland is likely to be about 10 million, of which 46% are ferrous sulphate, 46% ferrous gluconate, and 8% ferrous succinate

Summary and Conclusions

Ferrous-sulphate tablets, with or without added trace elements, proprietary or non-proprietary, are the cheapest preparations of iron at present available for oral medication Since ferrous sulphate raises the hæmoglobin level as effectively as ferrous gluconate and ferrous succinate, and, when given in comparable doses of elemental iron, is no more liable to cause side-effects it is the preparation of first choice for oral iron therapy

In hospital practice the amount of ferrous sulphate prescribed (46%) is slightly less than the total for the newer organic preparations (54%) The prices of the different tablets vary considerably, depending on the manufacturer and on the quantity purchased, but, using the lowest price for each preparation, the cost of iron tablets to the hospital service in Scotland each year can be calculated to be at least £3000

In family practice, however, ferrous sulphate is prescribed considerably less frequently (23%) than the more expensive organic preparations of iron (77%) From the data present in this paper the cost of the iron tablets used by the National Health Service in Scotland is calculated to be £6500 per month

If ferrous sulphate were always prescribed in preference to ferrous gluconate and ferrous succinate the saving to the N H S in Scotland would be, at a conservative estimate, about £1800 in a year for hospital practice and £3250 a month for family practice—a total of almost £40,000 per annum

If it is accepted that the ferrous compounds mentioned above are similar in therapeutic efficiency provided that the daily intake of iron in each preparation is the same, and if it is agreed that the standard effective dose of ferrous sulphate is one tablet three times daily (180 mg of elemental iron), then the equivalent dose of ferrous gluconate and ferrous succinate would be five tablets per day (175 mg of elemental iron) On this basis the use of ferrous sulphate would lead to an even greater saving to the Health Service than the amounts suggested above

We wish to thank Sir Kenneth Cowan, of the Department of Health for Scotland, for giving us permission to publish the prescription survey and for providing details of the number of hospital beds in Scotland We are also grateful to those physicians and pharmacists in different parts of Scotland who supplied us with data regarding the iron tablets used in their hospitals

CONSULTANTS AND OTHER SPECIALIST STAFF IN HOSPITALS

THE Ministry of Health and Department of Health for Scotland have issued tables that will be of special interest to those intending to train as specialists

Table I (not reproduced here) shows the age-distribution at June 30, 1956, of consultants and senior hospital medical officers practising in the various specialties It shows also the numbers of paid sessions undertaken by the consultants and S H M O s in each specialty for each year of birth

Table II shows the numbers of consultants in each of the specialties year by year from 1949 The corresponding figures for senior hospital medical officers are not available

Table III shows the number of senior registrars in each specialty on June 30, 1956, at the various stages of their training The column headed "Others" includes those holding "transitional" posts

All the figures relate to England, Wales, and Scotland

TABLE III—SENIOR REGISTRARS IN GREAT BRITAIN ON JUNE 30, 1956

Specialties	Training plan					Others*	Grand total
	1st year	2nd year	*3rd year*	4th year	Total		
General medicine	39	40	30	27	136	68	204

Consultants practising in more than one specialty have been included under each Table includes honorary consultants

HOSPITAL COSTS

In England and Wales the cost of our hospitals has grown from £219 million in 1949–50 to an estimated £421 million in the present financial year This is a colossal sum, but the gross national product—the most straightforward measure of the country's total resources—has risen even more rapidly, as was clearly shown by Abel-Smith and Titmuss[1] Part of the increased cost merely reflects the falling value of the pound But other factors are at play First, the population of England and Wales has increased in the past ten years Secondly, there are more elderly people in the country, and their demands on hospital services are greater than those of the general population Thirdly, the hospital service has been slightly expanded, and it is dealing with many more patients Staffed beds have increased in the decade from 448,057 to 476,870, and admissions have increased from 2,937,000 in 1949 to 3,794,000 in 1957 Fourthly, the length of stay, especially in maternity and mental cases, has been curtailed, people are getting well faster, and it is usually the early days of hospital care, when so much diagnostic work has to be done, that cost the most Finally, modern hospital techniques are more expensive than those of former years

NEW YORK

So much for the local scene, but England and Wales are not the only countries with problems of cost In the New York area the seventy-four voluntary hospitals and convalescent homes report an operating loss of $23,500,000 for 1957—an increase of $3,550,000 over the 1956 figure[2] This deficit takes no account of, on the one hand, receipts from philanthropic sources and income from investment and, on the other, hospital depreciation, interest on debts, and money spent on research and medical education It was estimated that the hospitals' net loss, including all income, was in the region of $6 million, this estimate includes an allowance of 5% for plant depreciation Meanwhile the operating income, including revenue from patients and from auxiliary activities which produce income, went up 6 8% to $176,000,000, and the operating costs rose 8% to almost $200 million

In the New York area hospital admissions have increased by 41% since 1946 In the production of motor-cars, the greater the number that run along the production line, the lower the cost of each, but in hospital service the reverse holds good speed and skill add to the expense Obviously no-one would want to change this beneficent advance, and, as one administrator said, "the deficit is a badge of honour" But hospital care, like pleasure, has to be paid for some time or another Many administrators in the New York hospitals and elsewhere feel that, if only the potential patients could be taught to appreciate the benefits of scientific care in reducing the period of illness, as well as cutting down suffering and anxiety, they would be ready to pay the enhanced price Dr Martin Steinberg, the executive director of Mount Sinai Hospital, says this[2]

> "One cannot define hospital service in terms of so many dollars a day or in terms of a specific quantity When the patient purchases hospital services, the quantity and its cost are determined only by the requirements of his illness and the capacity of the hospital to fulfil them"

But this partly begs the question Admittedly some patients would be able, and even more would be willing if they were able, to pay enhanced costs, but what about the many for whom the hospital bill spells ruin, or at least a crippling reduction of income, perhaps at the very time when extra benefits of food and fresh air are most desirable?

CANADA

The problem of hospital costs has been faced realistically in several of the Provinces of Canada The *Journal of the Canadian Medical Association* has issued the report of an interesting and instructive symposium which deals with various approaches[3]

Alberta

In Alberta[4] the first step towards hospital insurance was to establish a free public-ward service for all maternity cases This was heartily approved by the public, because the overwhelming majority of the women have their babies in hospital The profession also gave considerable support to the plan The next stage was to introduce what became known as the "dollar-a-day" plan, through which each patient pays that amount for a public-ward bed, the remainder of the cost being met by the municipality with help from the provincial Government The people strongly supported the scheme, but there was some resistance from the municipalities on the ground that the provincial contribution was not enough Nevertheless the entire province was covered within two years

This advance into the realm of public medical care was in time felt to be insufficient Many patients still had a heavy hospital bill to discharge on account of the cost of medicines, operating-room charges, and diagnostic services By 1945 these extras were absorbed by an additional flat-rate charge of a dollar a day, and this extension in its turn proved highly popular The waiting-lists became longer—in relation to short-term investigation up to as much as 22%

Saskatchewan

In Saskatchewan[5] the Hospital Services Plan has been in operation since 1947 The scheme was designed to remove the financial deterrent to hospital care and also to ensure that the hospitals received enough funds to provide an adequate service Most persons who have lived in the province for six months are required to join the scheme, unless they already qualify for complete hospital care through other approved plans Those taking part represent more than 92% of the population The one test is the need for hospital care, and the Plan pays for public-ward accommodation and all incidental costs such as X-ray, anæsthetics, and physiotherapy At the beginning of 1957 the limit was raised to $10 per day In the same year the hospital tax was fixed at $20 for self-supporting persons, with $5 for dependent children The maximum tax payable per family was increased to $45

On the whole the Plan has worked very well although it contributes little towards the capital costs of construction or extension, beyond the federal grants of $2000 per active bed and $1500 for each convalescent bed These grants have been matched by the provincial Government. The Plan is administered by the Department of Public Health and by staff employed by the Government The Hospital Association and the medical profession are purely advisory

In 1956 the average number of days in hospital for all patients was 10 4 Patients remaining in hospital for over thirty days represented 5% of all cases, and yet accounted for more than 31% of the patient-days This emphasises the need for more studies on the treatment of long-term illness, and especially on the care of these patients, wherever possible, outside the " acute " wards of the general hospital

---

[1] Abel-Smith, B , Titmuss, R. M *The Cost of the National Health Service in England and Wales* London, 1956

[2] *N Y Times*, June 2, 1958

[4] Morgan, H. V *ibid* p. 747

[5] Brown, J L *ibid* p 749

In 1947 the total expenditure on the Plan was about $7 5 million By 1956 the figure had risen to over $22 million, and the average cost per case (excluding the newborn) rose in these ten years from $46 61 to $124 46

British Columbia

The main features of the arrangements in British Columbia are as follows [6]

1 All persons, after a year's residence, are entitled to hospital benefits

2 Payments cover the acute phases of hospital care but not chronic illness,

3 Standard ward care which is covered includes the use of the operating-room and nearly all drugs and services except anæsthetics

4 For outpatient services required within twenty-four hours after an accident a charge of $2 is made

5 Inpatients (except welfare cases) are charged a coinsurance-rate of $1 per day

6 There are limited insurance benefits for residents of British Columbia who have to enter hospitals outside the province

In the early days of the scheme attempts were made to levy individual premiums and, later, to make payroll deductions, but in 1954 these were replaced by payments from general taxation by means of raising the social-service tax from 3% to 5%

In summing up the effects of Government-financed hospital insurance in British Columbia Watson [6] makes the following points in relation to hospital costs

> A look at the " business " growth of the insurance scheme shows an expanding picture Since 1948 hospital beds have increased by 37%, patient-days by 50%, and staff by 80% During the same period expenditure on hospital insurance has risen well over 100% On the other hand, salaries and wages have gone up 225% " The doctor, thinking of medical services and not of the big business statistics, sees a lop-sided progress The hospitals have been helped out of debt Their staff has increased The hospital worker has had his standard of living increased remarkably Ironically, however, the beds available, the patients treated and the diagnostic and therapeutic advances have accounted for the smallest percentage of the increase "

Federal Legislation

The position in Canada is likely to change as a result of the Hospital Insurance and Diagnostic Services Act of 1957 [7]

> This enabling measure provides for a contribution by the Federal Government of 50% of the cost, more or less, to any province which agrees to make insured hospital services available, on uniform terms and conditions, to all residents of the province so entitled under provincial law, and without charge to the residents except *a general charge by way of premium*, or other amount unrelated to a specific service, and except authorised charges The Act does not cover hospitals for the tuberculous or the mentally ill Capital expenditure and debts are also excluded Each province will decide how it will raise its share of the costs—whether by premium or taxation

One effect is likely to be an increased demand for hospital care—up to a " plateau " estimated at about 7–8 beds per 1000 population

WIDER LESSONS

These findings direct attention to matters requiring further consideration in Britain and other countries First, we must be ready to examine hospital costs on a basis which offers real opportunities for comparison between one country and another Secondly, the rise in costs should be carefully related to other features in the national economy, including the general increase in prices, the growth of population and the demand for institutional services, and, not least, the urge towards higher standards of living It is by no means easy to devise criteria of cost which will satisfy the demand for accurate comparison between one country and another, but the idea is worth far more than a passing glance

Such a study should help us to detect economies that might be made without loss of efficiency, and particularly the point at which hospital care could well be exchanged for home care We might then be better able to decide what types of patient could be transferred, on good medical grounds, from the highly specialised attentions of the " acute " ward to simpler and perhaps more appropriate accommodation

---

The Wider World

MEDICINE IN THE NEW INDIA

R E Rewell
M D Lond, M R C P
PATHOLOGIST, THE WOMEN'S HOSPITAL, LIVERPOOL

For two years, from early 1956 until early 1958, I was in India, having been invited there under the Colombo Plan Working entirely among Indians, with Indians and for Indians, and counting as a class I officer of the Government of India, I obtained an insight into medicine in the country such as is not possible for anyone paying a brief visit

Western medicine on the British model has been established in India for a long time for example, the Government General Hospital in Madras claims to have been founded in 1677, and much of the present building was designed by Florence Nightingale British methods of teaching predominate, British textbooks are used, and English is still the medium of instruction The present generation of educated people think and talk in English, and this language is unlikely to be replaced by Hindi for a long time, especially in South India where Hindi is regarded as the more foreign

Indeed British methods persist in every activity, especially in government and administration and perhaps it is the persistence of this edifice that has prevented the country from sinking into chaos Unfortunately, however, the system was not designed to give freedom at the periphery, and the vested interests of people who have been in it for a long time have increased its rigidity Europeans long in the country told me how little was the difference to them when the few British at the top were replaced by Indians, and indeed there were *few to replace* 77% of foreign investment in India is British, and the number of British technicians and business administrators in the country is greater than ever Indians regard the British domination as one episode in their country's long history—inevitable in the circumstances and nothing to be ashamed of Newspapers always *refer to their present* " independence ", and there is no double talk of " freedom " or " liberation " Sastri [1] presents the background to this

British policy in medicine has been continued in many ways. Thus one of the recommendations of the committee on the medical services, formed in 1941 with Lieut.-General Sir Bennett Hance as chairman, was that institutes for postgraduate training should be established throughout the country, where there were suitable facilities and teachers, and these are now being set up. The Institute of Obstetrics and Gynæcology is at the Government Hospital for Women and Children in Madras and I was invited there as first professor of pathology. It was intended originally that these institutes should eventually move to Delhi and form part of a central Institute of Medical Sciences, but now a much smaller central institute is starting up, while the peripheral ones are to continue.

Some improvements in the organisation of medicine have been introduced recently by the central Government. Thus the standard of the qualifying examinations has been made uniform at an internationally accepted level. The diplomas of the various States have been abolished, retaining only the M.B. of the universities, and central inspection of the examinations has been undertaken. There is, of course, reciprocity with many Commonwealth countries. A number of new colleges have been opened, new buildings being erected, and senior staff trained specially, many of them abroad. Though unable to visit any of these colleges, I heard much about them from younger colleagues who hoped to transfer to them.

THE DOCTORS

The doctors among whom I was working were a hand-picked bunch, but I found the general standard of medicine higher than I had expected. In his own surroundings the Indian is far more adaptable and resourceful than he often appears in an alien environment, nor is he as self-conscious. After the first shyness had worn off I found postgraduates well informed and energetic in discussion, and, as with us, methods of teaching are far more by informal rounds and discussions than by formal precept and lecture. The Indian doctor works among ignorant and depressed people who regard him as a superior being, patients are too poor to pay much and there is heavy competition from cheap quacks. (These include practitioners of Ayurvedic "medicine", a system based on the old humours[2] but encouraged by the Government.) It is surprising, then, that almost all the doctors remain keen and alert and continue to think of what will be best for the individual patient. They tend to emphasise their membership of the international army of medicine at the expense of local knowledge: thus they will quote British and American statistics when these are not applicable (although often there are no comparable Indian figures). However, they know well enough the circumstances of their own compatriots and I myself found that adaptation of Western knowledge to the social conditions of the patients was not difficult, given a readiness to inquire and to learn. Indians of education are very willing to help in this, and do not object to inquiries made in the proper spirit, even when concerning religion. I heard of an understandable tendency among undergraduates to regard the humble villager as a lower species, but this is evidently soon rectified by the chastening discipline of practice.

I was told that there are about three times as many candidates as places at the medical schools. A fifth are reserved for women and others for members of the "scheduled castes". The curriculum is based firmly on the British model. Some interesting experiments with it are being made at the Christian Medical College at Vellore, but this, like all missionary enterprises now, works under a strong and continuous barrage of criticism and discouragement from the Government. The whole concern is a free gift from private individuals in America, Australia, and Britain, and its senior staff is drawn from those countries, but its achievements are claimed as "Indian".[3]

CONDITIONS OF WORK

Government schemes are by no means all helpful to progress. Not only is the administration rigid but the Oriental genius for red tape and procrastination, especially over finance, has to be experienced to be believed. My own work was much curtailed by this.

Most unfortunately the semi-military control of personnel has been retained, and even senior people are "posted" (with no warning and without being consulted) by the D.M.S. who rules the medical service of each individual State in the Indian Union.

Promotion is entirely by seniority within a specialty, there is virtually no competition for appointments, and in a hospital all authority is in the hands of the senior member of the staff as superintendent. Because people are moved so often, the staff of a hospital becomes quite unstable in its composition. Even at the earliest stage, trainees are "selected" arbitrarily for the various courses or appointments that will lead to higher degrees. Unless one is chosen in this way, one has no chance of specialising within the hospital service. Except for those still belonging to missionaries, all the free hospitals, including the teaching ones, and almost all the research institutes, are run by the State Governments. Even in the non-clinical departments of the medical schools, the appointments are made by the local D.M.S. and accepted by the university. The new postgraduate institutes are attached to universities, and the senior jobs in them rank in the academic hierarchy, but here again almost all appointments are made by the local D.M.S. Wherever they may have graduated, the postgraduate students are admitted to the higher degrees of the local university. We had graduates from as far apart as Cambridge and Calcutta. There is nothing corresponding to the diplomas of our Royal Colleges.

The pay of doctors is extremely low, even by local standards. A specialist in his 30s is unlikely to have more than about £300 a year and can get little extra from part-time private practice. A senior professor may get as much as £900 a year without private practice. The retiring age is still 55. Of course, some senior people make large incomes in private, and many distinguished consultants have no hospital appointment. Nursing-homes and private hospitals of all grades flourish. Many of the younger people resign from the hospital service as soon as they have their higher degrees. The diplomas of our Royal Colleges are still very popular, and I am sure will continue to be so, especially as they are the only alternative to the Government's rigid system.

Pay becomes worse the further one goes from the centres, yet it is at the periphery, among the unchanging villages that cannot afford to support doctors, that they are needed most. One is always reading exhortations from elderly politicians to educated young people to go to work in the villages, but they are expected to go about on foot, live in mud huts, cut themselves off from all hope of refresher courses and of promotion, and be content with a pittance. Such dedicated souls exist in India as in all countries, but naturally there are far too few to do what is essential. In obstetrics the position is very bad because far more women than men are being trained Almost all are married, and, though they are able to go on working, they cannot leave their husbands to go to the villages India being a democracy, a member of the hospital service is free to resign, and he will certainly do so rather than be posted to a village He can get better pay abroad, e g , in the U K or Malaya—and so many of the best young people are exported This applies to other fields besides medicine I found that gold-field technicians were still being attracted to South Africa (of all places) by the pay

THE HOSPITAL AND INSTITUTE

We admitted about forty postgraduates each year, nominated by the medical services of the various States of the Indian Union They had a year's course for a diploma, which almost all obtained, and about half went on for a second year to sit for the Madras M D , which about five obtained The average age of students was rather high at first, but is coming down as people who obtain priority by seniority are passed out As the hospital undertook about 13,000 deliveries and 5000 operations each year, they had plenty of material

Fortunately money had not been lavished to make a show place for distinguished visitors, and we still had the old open airy wards with wide verandahs The poor-class Indian does not understand or like a bed, and so is kept in one only as long as the nurses find it more convenient After this there is a mat on the floor Many of the patients came from long distances, all were poor and mostly illiterate, few received antenatal or postnatal care, and reattendance and follow-up were virtually impossible with our resources Anyone needing long-continued treatment had to be kept in for the whole time, and immediate admission from outpatients was essential Some had been seen by a doctor outside, others had been treated by such people as the local barber's wife, who is the hereditary midwife in an Indian village, while others simply arrived on foot or in a rickshaw and told their tale The number of patients thus has to be, and can be, expanded considerably as required A new building to house laboratories, library, &c , is projected, but fortunately is to be in the old simple style

The average family income of patients was about Rs 40 (£3) per month, and their degree of anæmia and of infestation corresponded The average age at marriage was just over 14 years and at first delivery just under 20 [4] Prolapse was common and severe and also vesicovaginal fistula Much stress is laid on "family planning", but many came for sterility too because it carries grave social disabilities

The patients stood surgery very well despite severe malnutrition and anæmia After a normal delivery the woman would be sent home in forty-eight hours Of course, we saw many specifically tropical conditions—filariasis, malaria, amœbic dysentery—but this hardly affected gynæcological treatments, which differed only in small ways from those seen in the West The medical staff of all grades were most keen and competent Their practice was based on advanced British and American ideas and they easily adapted their Westernised knowledge to the background of their patients Most of the seniors had been abroad for work and study, usually to the U K., U S A , Canada, or Sweden

I found the standard of laboratory medicine good wherever I went in India, but it is confined almost exclusively to academic centres Buildings and equipment are simple—except in a few very favoured places—but adequate I felt that on the whole they had spent the small available funds to good advantage and had avoided frills Biochemistry is largely in the hands of science graduates, but not bacteriology Blood-transfusion is neglected The old-established research institutes continue in being and some new ones have started, especially in the all-important subject of nutrition, but there are still too few and they are hampered by the arbitrary selection of staff Our institute was very research-minded, and the suggested investigations were usually carried out by juniors specially posted by the D M S on request These young people had a very varied background but seemed to tackle the work well under supervision The amount of Indian original work which reaches print seems to be very small compared with the effort put into it, but it is hard to see just why this should be so

The best technicians in our sense of the term are junior science graduates, classified as "assistants" Lower grades are not well trained, and indeed most ancillary staff are of poor quality because deliberate policy keeps the number of jobs high and the pay low This may still be necessary in India, but the Western visitor becomes irritated by the rows of peons asleep on benches and of clerks who cannot type accurately Many of the routine chores are done by junior medical staff who stay too short a time at them to become skilled

Of nursing I was unable to judge, but I understand from visiting experts, and from those who have been under their care, that Indian nurses can be described as moderate They are kind and attentive, but most are lacking in advanced techniques Their pay and conditions of service are relatively rather worse than those of doctors Many more are needed urgently, especially midwives

The main object of the institute was, of course, teaching, and for this we had adequate facilities, firstly in the flood of material, secondly in the quality of the teachers, and thirdly in the equipment Much of the teaching was informal, but seminars and lectures were held We had a cool lecture room, projectors, tape recorders, and good photographic equipment, with a trained "photo-artist" who also assisted students to prepare their "books" of cases—an examination requirement obviously based on that for the M R C O G We had a small museum which we recatalogued and enlarged We took a fair number of the world's journals relevant to the work, but there had not been time to build up a library We all relied heavily on the library of the British Council, which has a very good and up-to-date medical section, containing many of the summaries of recent work which are so useful to postgraduate students Indeed the British Council is very active and influential in India

Unfortunately necropsies were almost impossible to obtain Junior doctors shrink from asking for them, but the seniors have even attempted to introduce legislation to facilitate them I had not realised how important they are until I was without them

GENERAL BACKGROUND

Social

Working with enlightened and friendly colleagues and students, it was often difficult to remember how different was their background from my own, but we must do this if we are to understand their problems and especially if we are to help Indians who come to this country and are uprooted from their own culture

The ancient organisation of caste and family was described once and for all by Dubois,[5] and the account has been brought up to date by Thomas.[6] Some recent writers, such as Carstairs,[7] have implied that it is now confined to a small section of the people, but, in South India at any rate, it is still almost universally valid, although in the cities there is little evidence of it to the casual observer. The great majority still live in the old way, all the sons, with their wives and children, remain under their father's roof, the wives do not speak to their husbands in the presence of their mother-in-law, and marriages are arranged by the parents. Unless destined to go to a university, girls in enlightened families are still married off at the minimum legal age of 16, while in poorer and more backward families this minimum is generally disregarded. Like so much recent legislation apparently directed against ancient wrongs, that against child marriages is so worded as to be easily disregarded in practice.[6] Despite forecasts to the contrary (e.g., Wheeler[8]) this way of life has probably become more rigid since independence. The various "communities" do not mix with each other in their own homes, and I am sure that this—not European standoffishness[9]—is why mixing between Indians and Europeans has always been so difficult. Outside their homes, mixing is now general in the cities.

Economic

India is an overcrowded country with an impoverished soil and few industries as yet. The cow is sacred: innumerable semistarved brutes crop all the young vegetation, producing very little milk, and lack of wood leads to their dung being used as fuel instead of as manure. The only animal protein that many people will take is curd made from the milk of cow or buffalo, but its scarcity makes this expensive. Meanwhile the population increases.

India then must industrialise, and faces the now familiar problem of how to do this rapidly without inflation and profound social dislocation. Medicine cannot claim an undue slice of increased productivity, but, without disparaging what has been achieved recently, I am sure that much more could be made of the resources available. The methods of administration are extremely wasteful, and in any case it is an insult to responsible, trained, and honest people to tie them up with red tape as is done. This treatment has to be experienced to be believed. Doctors in hospital must be allowed much more say in nonclinical and administrative matters than at present, they should also have some security of tenure in senior posts, and better methods of promotion must be devised. With the present expectation of life the retiring age should be raised to 60: by preventing waste of skill this would save money. Most important of all, the periphery must be made attractive. It is there that the real work is to be done, and it is there that at present nobody will go if he can possibly avoid it. On the practical side medicine is keeping up well, and fortunately practitioners are striving to maintain a place well in the mid-stream of present-day medical thought. To continue the use of English will certainly help to keep them there. (The only subject in which no regard was paid to accepted opinions appeared to be fæcal hygiene.)

NEED FOR HELP

India remains a poor country and needs help to raise herself. Western experts are welcomed, and every facility was given me by the people with whom I was actually working, the atmosphere was most friendly and I soon felt myself to be one of the team. In spite of the shortage of trained people, there is no room in India now for the European doctor to settle. Indians intend to keep their own jobs for themselves and cannot understand how we in Britain admit people from other Commonwealth countries or European refugees. But organisations like the Colombo Plan allow British doctors to give their help for a time, without personal loss and indeed with gain in many ways.

I am extremely glad that I went to Madras. The officials of the Commonwealth Relations Office, both in the U.K. and in India, were most helpful, and my pay and conditions of service were very good. Pay is very important, because a high standard of living is necessary for us to maintain efficiency in a difficult climate. My conditions certainly were very much better than those of people whom I met working for the World Health Organisation.

Conferences

WORLD FEDERATION FOR MENTAL HEALTH

THE 11th annual meeting of the Federation, held in Vienna from Aug. 24 to 29, had nearly 500 participants from 34 countries. Its main theme was uprooting and resettlement.

Dr BROCK CHISHOLM (Canada), the president, in an address called Man's Responsibility in the World, spoke of the continued existing of second, third, and perhaps fifth class citizens, who are deprived of certain rights, and of the ridiculous people who still judge by such signs as colour of skin. There are very few communities without some degree of discrimination. Describing the way in which children are being prejudiced in early life, he recognised five abilities as necessary for the assumption of responsibility in the world today:

1. The ability to face and accept facts and act upon them.
2. The ability freely to change attitudes independently of parents and forbears, and without guilt and anxiety.
3. The ability to live without discrimination and prejudice.
4. The ability to love without discrimination and prejudice.
5. The ability to make discoveries, and to appreciate what is discovered.

He drew attention to the pitifully small proportion of research effort that is devoted to mental health and to human behaviour.

Refugees and Immigrants

Dr MARIA PFISTER (W.H.O.), discussing Resettlement as a Sociological Problem, pointed out that the more coercive the conditions in which resettlement takes place, the stronger the regression in the behaviour of both parties, and that in periods of crisis this will bring out stress that is only latent at other times. Another very important factor is the degree of uniformity or diversity of the social ideal held by the two parties.

She came to the general conclusion that, whenever possible, there should be a phase of planning and preparation for migration for both parties. In any resettlement there must be a "catalysing" team which is briefed with knowledge of the factors influencing both parties, and it should be constantly asked, "how does one resettle?" Mass action is the arch-enemy of mental health in resettlement. Families must be sent as single units, and there must be no separation of children from parents. In all resettlement processes there is a great need for time, and this is a need which few Europeans know instinctively.

Mr ELFAN REES (World Council of Churches) gave some impressive facts about the 40 million people driven from their homes since the close of the second world war. They form a third force in society—the proletariat of the dispossessed. He reminded the meeting that, besides a

camp psychosis, there is an out-of-camp psychosis—the attitude of refugees who do not want to leave a camp

Prof Erik H Erikson (U S A) spoke of the normal identity crises—for example, during adolescence or in any major change of status, or during involution Just as normal people will react differently to these identity crises, so will refugees There is a positive side to the refugee position, in that a person who has never felt uprooted may never have had a strong positive sense of being at home If he has never been isolated, he may never have found an identity To become an alien may for some people be to become mature

Dr H Strotzka (Austria) outlined the work of the Austrian Society for Mental Hygiene in establishing teams to tackle the mental-health problems of the 183,000 refugees passing through Austria Counselling services and other medical attention was available in such a way that, though there was much disturbed behaviour, no refugee was sent to a mental hospital It was seen that such admission would hopelessly compromise the future of the individual refugee From experience Dr Strotzka emphasised the terrible effects of lack of information and communication, in spreading mistrust and paranoid attitudes

Prof Dan L Adler (U S A) described the Psychological Problems of the Voluntary Migrant to Australia

A study of the response patterns of more than 400 immigrants of various nationalities was made, and compared with over 200 Australian children's responses This showed how the various patterns of family behaviour, such as the mother's or the father's autonomous behaviour, tended to approximate to the general Australian pattern, from quite diverse original patterns, within about six years Also, it seems possible to interpret parental dissension as an index of general tension The main hope of the Australians in respect of the refugees is in the children rather than in the existing families

Prof John C Sawatsky (Canada) talked about the settlement of 400,000 immigrants in the metropolitan Toronto community, where they now form almost a third of the population Favourable conditions allow the immigrant families to make a simple transition, but it is for the children to complete this process

Dr Kenneth Soddy (scientific director of the Federation) summarised the reports of the 13 discussion groups on various aspects of the refugee situation, the film discussion group, and the special conference of immigration officials which was held alongside the main meeting This conference was attended by senior health and welfare officials of the main countries with extensive immigration programmes This informal conference of Governmental representatives made a number of recommendations for the improved handling of refugee programmes

Prof Hans Hoff (Austria), president of the Federation for 1958–59, gave an address on Home and Identity, in which he spoke of the importance of landscape, history, and past experience on the future happiness of migrants, and the need to take account of these factors and apply them scientifically

Past and Future

The first Dr Mary Hemingway Rees memorial lecture was given by Dr H V Dicks (London), on Mental Health in the Light of Ancient Wisdom All the great ancient religions, he said, want man to be happy, good, and free, and they all agree on the threefold need for adjustment, self-realisation, and integration This is part of the aspiration of mental-health work

At the general session, Dr J R Rees, director of the Federation, outlined some of the plans for an intensive programme of international work for the World Mental Health Year, with five main themes

1 The needs of children (the family in a changing world)
2 National surveys in the field of mental health and ill health
3 Teaching about mental health (professional people and other workers)
4 Mental health aspects of industrial change (human relations in industry)
5 Psychological aspects of migration

EUROPEAN LEAGUE FOR MENTAL HEALTH

On Aug 23 the European League met in Vienna under the presidency of Prof Hans Hoff

The Older Worker and Retirement

Dr Doris Odlum (London), immediate past president, opened a discussion on mental health problems of the older worker and of retirement She pointed out that nowadays more people retain much of their vigour and working capacity until the late 60s or even later, but on the other hand many people even in the 50s cannot get suitable employment and some are arbitrarily retired long before their capacity for efficient work has diminished The result is not only a serious loss of man-power but also, often, considerable disturbance of mental health

Few people give up work voluntarily merely because they want more leisure in fact, many dread the prospect of idleness, they feel discarded and lose their incentive, which can lead to *premature deterioration Unlike older women with homes and* husbands and perhaps grandchildren to care for, the retired man may not be wanted in the home or indeed anywhere In the case of widows, or widowers, or the unmarried, loneliness is often one of the greatest problems

The preventive and remedial measures which Dr Odlum discussed include the provision of more suitable work, part-time work, and the avoidance of compulsory retirement as far as possible Employers, local authorities, and voluntary agencies could do much to prepare people for retirement, to provide activities and interests, and to maintain social contacts

The problems seem to be similar in all industrialised communities and especially in countries which are being rapidly industrialised The pattern of living is changing too quickly for older people to adapt themselves, also the situation is less favourable to them than that of an agricultural community

Prof Paul Reiter (Copenhagen) said that it is now realised that many cases thought to be senile psychoses are really psychogenic and can be greatly helped by medical and social care

Dr André Repond (Switzerland) remarked that the problems of the agricultural communities are considerable and not to be ignored Their pattern of life, too, is changing He wondered whether the *old are* unhappy Have we any real knowledge? If they are, what is the basis of their unhappiness? Perhaps it relates rather to their earlier frustrations and emotional conflicts than to the present

Dr Claude Veil (France) pointed out that preparation for ageing really begins in childhood and at school The lower the standard of education and cultural background, the earlier the decline of mental powers He agreed that men would benefit from learning household arts and activities *as children Some people seem never to be at the right age* it is either "you are too young", or "you are too old"

Dr Socken (West Berlin) said that people who have a religious background or a feeling of purpose adapt much more happily to increasing age

ISRAEL MEDICAL ASSOCIATION

THE fourth World Assembly of the Israel Medical Association was held in Tel Aviv on Aug 12–24 The assembly is now a triennial event, and this year it coincided with the celebration of the tenth anniversary of the State of Israel.

Prof **HERMAN ZONDEK**, honorary chairman of the conference, remarked that scientific thought had been largely dominated by the mechanistic doctrine of causality, but, despite much progress, the riddle of life had not been solved The physician in our time was called on to take a greater part in public life than hitherto, particularly in his contribution to education "The younger generation, drunk with the progress of technology, looks upon an empty soulless world Humanity in our time is sick, suffering from numerous endogenous ailments of moral, political, and economic kinds, and from extraneous threats to its very existence, the most dangerous of them the unchaining of atomic power Humanity will with difficulty get rid of this threat, it seems easy to die with the atomic bomb, but how shall we live with it?"

Public Health

Dr S **BYESH**, director-general of the Israeli Ministry of Health, said that the health of the Jewish population of Palestine in 1948 was fairly good. With immigration were introduced many carriers of disease and susceptible persons The lower standard of living, the lack of proper housing, and the ignorance of the immigrants in matters of hygiene resulted in deterioration of the health of the people, culminating in an increase in infant-mortality and crude death-rate, and in the spread of tuberculosis, poliomyelitis, and malaria

Intensive health measures had resulted in effective control of most of these conditions, and at the end of the ten-year period the health conditions of the country compared favourably with those in the U S A and most European countries

There was 1 doctor to about 450 inhabitants, and there were about 3 general-hospital beds to 1000 inhabitants

Prof G G **MER** said that malaria in Israel is dying out The present low incidence had been accomplished by control of anopheles breeding, the use of residual insecticides, and efficient medical services The occurrence of a few scattered cases pointed to the presence of human carriers in the country Because in the neighbouring countries, too, intensive anti-malaria work was being carried out, the complete eradication of malaria in Israel could be regarded as a certainty, provided immigration of malaria carriers could be prevented and the present number of carriers could be reduced

Serum-lipids

DR. D **BRUNER** said that the population was now composed of, on the one hand, European Jews, among whom there was a high incidence of coronary-artery disease in middle age, and, on the other hand, Yemenite Jews, who were practically free from atherosclerotic heart-disease in middle age Of 32 Yemenite farmers who had been investigated, none had had a level of β-cholesterol over 180 mg per 100 ml , and 27% of the total cholesterol was bound to the α-globulins In this group the percentage of α-cholesterol was nearly double that in a group of patients with ischæmic heart-disease and a third higher than that in healthy European Jews

Mediterranean Fever

Dr H **HELLER**, Dr E **SOHAR**, and Dr L **SHERF** reported that the great majority of patients with familial Mediterranean fever were non-European Jews, and the second large group consisted of Armenians The disease began in childhood or early adolescence and persisted for many years It was characterised by recurrent attacks of fever accompanied by abdominal pain, arthralgia, chest pain, and sometimes skin manifestations The attacks were brief, usually lasting for twelve to forty-eight hours, and recurred at irregular intervals During the abdominal attacks signs of peritoneal irritation usually appeared In X-rays of the abdomen fluid levels were found in the intestinal loops A small transient pleural effusion might be detected in chest films Joint pains might be restricted to one joint or might attack several at a time, sometimes the affected joint was warm, red, and swollen, and fluid might be found in the synovial sac, joint manifestations usually declined more slowly than the others Between the attacks the patients were well The disease terminated, in some cases, in renal failure and death due to amyloidosis Extensive laboratory investigations had revealed very high erythrocyte-sedimentation rates, high fibrinogen levels, and slight spherocytosis In many cases proteinuria was found as well Therapeutic measures were of no avail No patient ever recovered, but remissions did occur During pregnancy complete remission was usual The clinical picture, as well as the familial incidence and the limitation of the disease to certain ethnic groups, suggested that the cause was an inborn error of metabolism

Pneumoconiosis

Dr E E **LIEBER** (Great Britain) described an inquiry into whether the dust and vapours from various chemical substances could cause chest disease He pointed out the importance of medical and radiographic examination of affected persons and of skin-sensitivity tests The substances involved included (a) dusts (such as glass monofilaments from the cutting and handling of mats, cloths, rovings, and beryllium-copper alloy, fine-glass and epoxy-resin dust, and polyester dust) and (b) vapours (styrene from resin compounding and mixing, and methylethylketone peroxide accelerator) In some patients who came under his care there was a reduction in vital capacity, and chest radiographs showed occasional lung markings and sometimes emphysema The prognosis in all cases was excellent. The patient's condition did not continue to deteriorate after removal from exposure, and this dust disease might be described as a "benign pneumoconiosis" Dust-extraction equipment and the usual additional prophylactic measures protected workers engaged in handling glass fibres and epoxy resins

Dehydration

Dr M **TOOR** said that workers in the Dead Sea region in the summer drank 5 5–10 litres a day Despite this intake, outdoor workers showed signs of dehydration, manifested by weight loss, hypernatræmia, slight metabolic acidosis, and relative hyperchloruria The daily urinary output was in some as low as 300 ml Hyperventilation, present at rest, increased after work The sodium-potassium ratio in the saliva decreased after work In order to determine the influence of varying water intake, 10 fully acclimatised subjects had been examined after they had walked for two hours at 6 km per hour The outdoor temperature was 42°C They were divided into three groups (*a*) without fluid intake, (*b*) without limitation of fluid intake, (*c*) with forced fluid intake The group without fluid intake had shown an average rise in body temperature of 1 9°C and an average drop in body-weight of 1225 g per hour The glomerular filtration-rate was low and little urine was excreted, the alkali reserve remained unchanged, but the pH dropped slightly The group which drank according to inclination lost 400 g body-weight per hour, and the average body-temperature increased by 0 7°C The group with forced water intake drank nearly 2 litres per hour and gained 500 g per hour in weight, body temperature remained constant Their perspiration did not increase in direct ratio to the water intake, but the glomerular filtration-rate, the amount of urine, and the urinary sodium increased. The alkali reserve dropped, but blood pH did not change This experiment indicated that fluid intake according to thirst urge was not sufficient, on the other hand, positive water balance could prevent disturbances in homœostasis even in the hot climate of the Dead Sea region

Before Our Time

ALFRED RUSSEL WALLACE
(1823-1913)

AT school I was given as a prize Wallace's *Travels on the Amazon and Rio Negro* I remember being puzzled when I read on the title-page the author's claim to be the co-discoverer with Darwin of the theory of the Origin of Species I had heard a great deal about Darwin but Wallace's name was new to me Many people must have been equally puzzled on reading the centenary articles which have recently appeared, for most of these, while starting off with the presentation of the two independent papers by Darwin and by Wallace to the Linnean Society on July 1, 1858, thereafter refer only to Darwinism Some account of Wallace and his relationship with Darwinism may therefore not be out of place

Alfred Russel Wallace was born at Usk, Monmouthshire, his father being nominally a solicitor but actually a lifelong idler Leaving school at the age of 16 he became a land surveyor and architect and later a schoolmaster He early became interested in botany, and a chance meeting with H W Bates extended his interest to entomology and in due course led him to spend four years on the Amazon (1848–52) On the voyage home the ship was completely destroyed by fire and most of his collection was lost In 1854 he went to Malaya, where he spent eight years in exploration and in pondering over the problem of evolution In the idea of evolution itself there was nothing new It had been adumbrated by Goethe (some people find suggestions of it in Empedocles and Ovid) and developed by Lamarck, and it was now engaging the attention of many thinkers, among them Herbert Spencer, Robert Chambers, and Sir Charles Lyell The unsolved problem was the cause of evolution

In February, 1858, while recovering from an attack of ague at Ternate in the Moluccas, Wallace suddenly recollected Malthus's *Essay on Population* which he had read twelve years previously and he at once realised that this gave him the key which he sought " There suddenly flashed upon me," he wrote, " the *idea* of the survival of the fittest " He hurriedly wrote out his theory and sent it to Darwin Darwin, also inspired by Malthus, had for many years been accumulating evidence on similar lines Lyell, evidently realising from his wider experience that a fundamental generalisation was imminent, had been urging him to publish his results lest he be forestalled Darwin, however, was in no hurry

On receiving Wallace's communication (the author being unknown to him) Darwin was dumbfounded " I never saw a more striking coincidence," he wrote to Lyell " If Wallace had my MS sketch written out in 1842, he could not have made a better short abstract Even his terms now stand as the heads of my chapters " On the advice of Lyell and Sir Joseph Hooker, Wallace's essay and an abstract of Darwin's conclusions were jointly read Though they were in general agreement, the views differed in certain respects In particular, Wallace early abandoned the Lamarckian doctrine of the inheritance of acquired characters, but Darwin adhered to it for the whole of his life, putting forward his complicated pangenesis theory in explanation

The simultaneous appearance from two sources of a revelation which shook the scientific and religious worlds might well have had unpleasant consequences But the very reverse happened So far from indulging in jealousy and acrimony, Darwin and Wallace became lifelong friends with the warmest mutual regard On the authorship of the theory they vied with each other in deference "You ought not," wrote Darwin, "to speak of the theory as mine, it is just as much yours as mine" To this Wallace replied " As to the theory of natural selection itself I shall always maintain it to be actually yours and yours only " This he certainly did, for in all his writings he called the theory " Darwinism "

On his return from Malaya Wallace began to write voluminously The most important of his biological books are *The Malay Archipelago, The Geographical Distribution of Animals* (which became a standard work), *Tropical Nature, Australasia,* and *Island Life* In *The Wonderful Century* he displays his interest in physics, chemistry, astronomy, geology, and cosmology

Unlike Darwin, who confined his activities to science, Wallace was interested in everything that concerned human welfare

At an early age he was attracted to Robert Owen's New Lanark experiment and later he was influenced by Herbert Spencer's *Social Statics* After many years' hesitation he became a socialist, numbering among his friends the leading socialists of the day He trenchantly poured out his views on capitalism, wages, poverty, and militarism To the emancipation of women he attached a peculiar biological significance, linking it up with the theory of natural selection He was convinced that if women became economically and socially independent they would select their mates with more discretion, so that " numbers of the worst men among all classes who now readily obtain wives *will be almost universally rejected* " He summarised his sociological views in *The Revolt of Democracy* and *Social Environment and Moral Progress*, both written in his 90th year

His special interest, however, was the nationalisation of land, a subject on which he felt that his early experience as a surveyor enabled him to speak with authority When, in 1881, as the result of an article which he had written in *The Contemporary Review*, the Land Nationalisation Society was formed he became its president and he retained the post until his death

Like so many intellectuals he was singularly naïve in medical matters

In *My Life* he relates how he was cured of asthma by living almost entirely on beef with small quantities of bread or vegetables, fruit, eggs, and light milk puddings This regimen he learnt through a friend from an American doctor named Salisbury who claimed to have proved that asthma, palpitations, gout, rheumatism, and other disorders were due to malnutrition caused by interference with digestion and assimilation through the excessive consumption of starch Wallace lapped all this up " Dr Salisbury ", he wrote, " has found for the first time in the history of medicine, a *cure*—not merely a *palliation*—for these painful and distressing maladies " He did not, however, propagate this opinion

More important is his violent opposition to vaccination In *Forty-five Years of Registration Statistics* and again in *The Wonderful Century* he claims to prove from the Registrar General's figures and other sources that vaccination, so far from preventing smallpox, actually increased susceptibility to it It was " a gross interference with personal liberty and the sanctity of the home It was utterly opposed to the teaching of sanitary science and one of those terrible blunders which, in their far-reaching evil consequences, are worse than the greatest of crimes "

While he was a schoolmaster he became interested in mesmerism, phrenology, and phreno-mesmerism, the last-named being a procedure whereby certain " faculties " were elicited in the mesmerised person by touching with the finger the part of his head indicated by phrenological teaching From this Wallace was led to spiritualism of which he became one of the most prominent advocates, regarding it as the greatest discovery of the century, surpassing even his own discovery of natural selection

In *Miracles and Modern Spiritualism* he gives a detailed account of the phenomena including those which he himself witnessed in this country and America Spiritualism was, in his opinion, superior to revealed religion " After death man's spirit survives in an ethereal body, gifted with new powers, but mentally and morally the same individual as when clothed in flesh " He enters upon an endless progression, the rapidity of which depends upon the extent to which he used his faculties while on earth Spiritualism thus provided a stimulus to moral behaviour during terrestrial existence Wallace was always careful to describe the phenomena as " preternatural " rather than " supernatural " His friends might scoff, but at least he was in the good company of Sir William Crookes and Sir Oliver Lodge

Financially, Wallace fell on evil days His income from his numerous books and lectures was surprisingly small and was reduced by injudicious investments and by the defalcation of a builder But this was not the worst In 1870 he accepted a wager by a certain John Hampden to prove that the surface of inland water was curved The experiment took place on the Bedford Level in the Fens, with the editor of *The Field* as arbiter and stakeholder Though Wallace was pronounced the winner his adversary, despite his felicitous name, defaulted, taking advantage of a legal quibble and making himself a bankrupt Unsubdued, moreover, by four prosecutions for libel and a term of imprisonment Hampden persecuted poor Wallace with the most scurrilous abuse for fifteen years Legal costs and the expense of the experiment reduced Wallace's finances to the lowest ebb In 1881, Darwin and Huxley persuaded Mr Gladstone to grant him a Civil List pension of £200 a year He died in his 91st year, his mind and pen active to the last Among the honours he received were the Order of Merit, the Royal medal and the first Darwin medal of the Royal Society, the hon LL D of Dublin University, and the hon D C L of Oxford University

Fearless and uncompromising, Wallace never minced his words The Joint-Stock Companies, he declared, swindled and plundered the public, the whole commercial fabric of the country was permeated with dishonesty, gambling, and robbery, while the administration of justice was thoroughly immoral He castigated scientific orthodoxy and was never so happy as when propounding or defending an unpopular thesis As may be imagined, his critical faculty often deserted him and he lacked a sense of proportion He was, for instance, ready to believe that spiritualists in the United States numbered 8–11 million, not stopping to reflect that this meant more than half the then existing adult population Though he did not believe in Christianity he was a confirmed deist He held that life could be explained only by postulating a Life Principle which implied a Creative Power, a Directive Mind, and an Ultimate Purpose which was the Development of Man, " the one crowning product of the whole cosmic process of development "

In England Now

A Running Commentary by Peripatetic Correspondents

MY work is full of meaning—or at least I mean it to be The only trouble is that I just can't see what it means Hints in plenty oh yes! But I can't get the meaning of them *Pro*meanings that's what they are, they only need activating Perhaps that's the trouble, my brain is deficient in promeaning*ase* it won't activate Or, half a minute it might be worse, suppose it's not just a deficiency state perhaps it's a toxic condition, perhaps my mind actively secretes an *anti*promeaningase How to neutralise this? Can it be bound to plasma-protein and taken to the liver for detoxication? *Degrado*antipromeaningase? What's that? Needs a co-factor? *co*-degradoantipromeaningase? Now we're getting somewhere I can almost see what it means

No! the pattern's lost again The nascent meaning showed a strong selective affinity for *anti*-meaning which converted it rapidly to inactive *meta*-meaning But that's what it all means! Promeaningase and anti-meaning are clearly in excess and therefore constant, so that we have a system of effective first-order consecutive reactions

promeaning→meaning→metameaning

and—oh but look how ghastly! This means that meaning has only a fleeting ephemeral existence after all I really do call that pretty mean, don't you?

* * *

Drinka Pinta Milka Day? You'll be lucky Our village has been shaken from taproom to shippon Joe Moffat has been booked for obstructing the highway Not, mark you, with the old green van that has the mudguards tied with binder twine, not even with the shiny new tractor We could have forgiven the Law for that Joe spends a lot of time in the Plough on market day No, it was far worse, he was run in for blocking the road with his milk cows It would never have happened in the old days P C Grimble would have got off his bike and helped to turn the herd in at the gate But not those new motor patrol chaps from the town they focused their radar on the backside of Buttercup and timed how long she took for two furlongs Joe got fined a pound and had to listen to a sermon on how to fit sixteen cows into the *Highway Code*

I feel very heavy-hearted about the whole affair The rolling English milk cow made the rolling English road There is some elemental simplicity about waiting for cows to move on Quite a different mood from fretting behind 100 tons of steel boiler or a surrealist aircraft fuselage on the trunk road All our motorists are fully conditioned to lowing herds winding slowly o'er the lea, even if they are not quite sure what is a lea It would be vulgar impatience to expect a cow to trot single-mindedly from grazing ground to milking parlour, and it would cost a lot more from the public purse to mow the grass verges No, there is something very soothing in slipping the clutch gently behind a herd of cows Those extraordinary pelvic bones protrude like the tail fins of a modern car how curiously pudendal have become the rear lights of Luton. One could muse on about following cows and cars, keeping a decent interval from the one in front But cars go on like that for hours all the way to Brighton ten minutes and two furlongs can pass a lot of cows

Of course, Joe knows my car If he thinks I ought to be off to an urgent case, he turns the herd with the dog, but that is not often Most days he just jogs alongside the open window, talking of life and country things, and poking incredibly unhygienic fingers into his mouth to whistle commands to Moss The herd really do not need a cow dog they have strolled the road for years And when they have turned in off the tarmac, Joe and I lean over the top bar of the gate and put the world aright Alas, those happy days seem gone A resolute tractor-mounted Moffat will have to punch his cows in the derestricted stampede of death on our roads Sixteen udders will sway in the churning rush, sixteen cuds will turn sour

All that will be left for us to say to you will be Eata Nounca Cheesa Day.

• • •

Each year at this season our city undergoes the ordeal of a festival of music and drama, and the hounds of culture can be heard baying in every close and wynd of the Old Town. But it is refreshing to be reminded that culture is not a prerogative of any particular income-group or intellectual coterie.

Yesterday I had to decline the offer of a game of golf with a senior colleague (a celebrated physician) because I was going to *Tristan and Isolde*. He was aghast. "What! Pay £2 and sit for five hours listening to all these Germans screaming away?"

This morning, at an autopsy on one of my patients, the mortuary porter kindly inquired if I had enjoyed *Tristan*, and added: "I've seen it twice, Wagner is very good, but give me Verdi every time."

• • •

On the coach on the way back I happened to be sitting next to him. His eyes were still alight with the fire of battle. "We will have them at the hospital," he said. We had been on our annual trip to the sea and our Administrator had spent the whole time on the dodgems. With his usual single-mindedness and determination, he had hurled his car against all comers, with dexterity and speed he had bashed and rocketed all other cars off their course. "The hospital will run on wheels," he exclaimed. "We will have them in the corridors and have dodgem parks outside each ward, at the front door, and all centres of activity. We shall have to ban all pedestrians. You can each have your own car," he continued generously. "We will give Matron and the sisters one each. We will have dodgem cars, dodgem stretchers and dodgem wagons for the stores. They won't be noisy, all electric, fixed with silencers. It will be quieter than it is at present. Of course we will have to have one-way traffic so there will be no bumping," he continued regretfully. "We might have an occasional Bump Day though," he added musingly. "Think of the time it will save. No more walking through miles of corridors." I imagined the Chief's round hurtling off from the front door to the back block and groaned to myself. "It will all stop at the ward doors," he said. "Of course, we shall have to cut them out on visiting days," he pondered, "the patients see little enough of their visitors already with television being on. . . ." I didn't listen any more. He was still talking rapidly. I fell asleep.

I think he really means to go through with it. Workmen have appeared in the corridors and a wire mesh is beginning to cover the ceilings.

Sophistication in the treatment of myocardial infarction is unbounded. After three days of frightening arrhythmias, electrolyte manipulation, and norepinephrine, my friend was well enough to state his own ideas on treatment. "Not by electrolytes alone" was his philosophy. So his wife and I, and a most enlightened hospital administration, have prevailed on a well-known string quartet in this mid-Western city to play for him. Every afternoon they trundle in, and they are at present wading through the Beethoven quartets. We persuaded them that atonal music might play havoc with his rhythm.

My friend's room is a very popular place these days. And his heart? Beating away in perfect time.

• • •

In that part of Yorkshire which will eventually comprise the South Riding it is an ignoramus indeed who is not aware of the St. Leger and of Race Week. At this time "failed attendances" in the outpatient departments may approach 50% of the total appointments, and those who do attend are in their Sunday best and apologise for troubling the doctor at such a time. Non-racing newcomers who fail to make note of this *jour de fete* may sooner or later find themselves at a disadvantage in the surgery; for in later months medical histories will include perhaps a cough which began "happen the month before race-week" or a pain which was previously experienced "the year Lupus came in first."

Letters to the Editor

EDUCATION FOR THE TROPICS

SIR,—I hope there will be a burst of applause, from spectators and players alike, for Mr. Wright's plea (Aug. 30) that education should take account of medicine in the tropics: a crescendo of delighted drumming would be more appropriate than polite handclaps from the pavilion.

In East Africa, to continue Mr. Wright's sporting simile, the game is much the same as in West Africa, though the pitch may be a little different. My strongest recollection is of rural dispensaries, of which in Uganda there are about 10 for every hospital, where the game may be at its simplest but the players are just as much in earnest. Here attends a third of the population annually,[1] and probably nearly *every* baby in its first year,[2] all to be seen by locally trained medical auxiliaries: there may be a small ward with a few beds, and the most powerful weapon is penicillin.

Common sense suggests that the rules of this game also should be taught—how to integrate these rural units with the hospital service, how best to make use of the times the doctor can visit them, what part they can play in prevention of disease, how much can be expected from the medical auxiliaries. Examples showing how other underdoctored countries have made use of such institutions would prepare students for this aspect of medicine in the tropics.

The educational, the social, and the preventive aspects of medicine are, as Mr. Wright so clearly argues, all-important in areas where there is so little background of health education, societies are so different from English, and successful prevention can reap such encouraging rewards. It is in these fields that physical *example* can play such a large part. To take a bad example, it is our own emphasis on "the *microscope*, the pill, *and the injection*" *that has evoked such a demand* for them from the local populations, and now the demand is often used as an argument for persisting with this disastrous imbalance (in Uganda, overall mortality under 14 years of age is 400 per 1000[3]). Another bad example has followed where no good example has been given: mothers are aware of the dangers of malnutrition, and therefore buy the imported baby-foods on which Europeans feed their children, but they can neither read the instructions nor afford enough—with the tragic result that malnutrition is aggravated. An encouraging response has followed the example afforded by a gift of skim milk powder from the Church World Service of the U.S.A.: in the child welfare clinics where this has been given away, attendance has doubled in the past two months. If the experience of other countries is repeated, the knowledge of the benefits of good nutrition will remain even when the gift has come to an end: the misfortune is that there are only a score or so regular child welfare clinics in Uganda at present—although there are about 900,000 children under 5 years of age.

One point to which I think Mr. Wright might have drawn more attention is that in the tropics the majority of doctors—certainly most of those associated with the kind of medicine he describes—are in the Government service. Now it is a strange paradox that under these conditions the fewer the doctors the less medicine (either preventive or curative) they seem to practise. Although surrounded by a fascinating variety of medical conditions, and in their monthly records accumulating figures of the greatest value for a public-health policy, the only figures which many are allowed to take an interest in are those of numbers of blankets or amounts on payrolls. In tropical Parkinsonism, office work expands to the exclusion of medicine.

Mr. Wright calls for "rural medical officers equipped with the necessary imagination and energy" and feels that the "centralised administration" has little part to play, and on this premise he builds his hopes for the value of better education for those going to the tropics. But in fact the administration has an all-important part to play. Medical officers, like other human beings, tend to concentrate on what their superiors show an interest in: if the director puts foremost the many aspects of medicine in the tropics, the M.O. will do likewise; if he puts foremost accounting, storekeeping, and administration, so will the M.O. The problem is how to ensure that the directors have the right outlook, and this, I feel, is beyond the scope of education.

BREAKING UP THE MENTAL HOSPITAL

SIR,—While applauding Dr. Baker's application of methods of combating institutionalisation, I think that several of his propositions (Aug. 2) require scrutiny.

Banstead Hospital, he says, now has 450 patients less than three years ago. Most mental hospitals have about 10% of their population on leave at any time, and if it were decided to discharge patients instead of sending them on leave their population would drop, but this is not necessarily a good thing. Dr. Baker does not tell us how many of the discharged patients have found their way into other mental hospitals or have committed suicide.

Banstead has a catchment area which includes parts of Westminster, Chelsea, and Battersea; the population is mobile, and it is reasonable to suppose that more discharged patients would move out of the area than into it. Furthermore several other hospitals take patients from the catchment area of Banstead, and some doctors would prefer to send patients to these because they do not agree that a voluntary patient should be required, *before admission*, to sign a form giving permission for electroconvulsion therapy, insulin, and any other treatment considered necessary.

The 40% rise in admissions given may include readmissions. It is not clear to me whether in the past many of these "admissions" would have returned to hospital during a period of leave.

Apart from the possible speciousness of statistics, a very important question arises if one looks at the effect of rapid discharge on the patient and community. Has investigation been made of the distress caused to the patient, his family, and others? Can Dr. Baker reassure me that in breaking up the mental hospital he is not breaking up the home? I wholeheartedly agree that businesslike methods are desirable in mental hospitals, but, whereas a business man takes the consequences of his decisions, the psychiatrist makes decisions which do not affect him: it is the patient and his family who take the consequences. There is a danger that the public may be made less tolerant to mental disease by having it thrust among them before adequate aftercare services are provided, and this in turn may hamper the development of these services.

I think it is generally agreed that a neurosis characterised by apathy, submissiveness, and loss of individuality results from factors arising in an institution. It is only in the past few years that this neurosis has been realised to have an ætiology separate from the mental disorder causing admission.[1] From visits to other hospitals and reading, it is my impression that many hospitals have introduced, and are introducing, programmes to stop causing this disorder and to cure it where it has been produced. Dr. Baker may think that dividing a large hospital into smaller units is a solution, but when examining this contention one should remember that hospitals built on the villa system with units of 30–50 patients also produced institutional neurosis in quantity and degree much the same as the hospitals with "barn-like wards" built in the Victorian era.

To say that the provision of hostel accommodation and sheltered workshops is not the proper function of a mental hospital seems to me a verbal quibble. One has has only to read Dr. Houston's imaginative article, A Project for a Mental Health Village Settlement,[2] and Professor McKeown's Balanced Hospital Community[3] to realise the possibilities of the future. I cannot see that mental hospitals can contract out of making such provisions.

Is it sufficient to treat the patient of today as the neighbour of tomorrow? Should we not aim at treating patients as we would like to be treated ourselves?

Shenley Hospital,

ULCERATIVE COLITIS

SIR,—We are grateful to Dr. Balfour Sclare (Aug. 9) for suggesting that the questionnaire in our paper of July 19 should have been given in detail. It was omitted to save space, but we would gladly forward a copy to anyone who cares to see it. The patients surveyed do not, of course, represent a "fair cross-section" of all cases suffering from ulcerative colitis: as they were all sufficiently ill to require an ileostomy, milder cases must have been excluded. However, we could say with certainty that every patient did suffer from the disease—which in a more comprehensive series could not be guaranteed. We are pleased that Dr. Sclare agrees with us on our proposed prospective inquiry on a longitudinal basis, but it is of interest that the present questionnaire method has already yielded information which is very close to that of the more detailed long-term studies of Engel. One of us (M. S.) had the opportunity of visiting Professor Engel in his clinic at Rochester, N.Y., after our paper was submitted, and a reconciliation of our statistics revealed many points of similarity: differences originally apparent were due to the methods of presentation.

We can understand the reactions of Dr. Ranyard West (Aug. 9) and Dr. Paulley (Aug. 23) to our inquiry. Most psychotherapists working with patients with ulcerative colitis are quite convinced of the psychological processes "that are causally connected with the symptoms in sufferers from this disease", yet the theories of these psychological processes are many and some are mutually exclusive. We shall not burden your readers with more references, but suggest again that they consult the papers of Engel which we have quoted. A psychosomatic hypothesis should fit in with the essential organic features of the disease and its natural history, and our *preliminary* inquiry into the order of appearance of symptoms in a very large (if not the largest) group of patients with proven ulcerative colitis does not encourage us to accept the existing hypotheses, but to study them even more critically.

We agree that psychotherapy in some patients is of value, but that does not support or prove the seven or eight psychosomatic hypotheses on the ætiology of the disease or tell us which is the most valid. Our paper (a joint effort by psychiatrist and surgeon) was not designed to prove that the condition was not due to psychological happenings. We are not prepared to accept the conviction of others—sometimes based on as few as two or three patients—unless they can be supported by proper evidence. We do not claim infallibility for our preliminary inquiry, but in reply to Dr Paulley's arguments against it we can only repeat "the value of the present method cannot be adequately tested by argument, but only by a carefully controlled prospective inquiry, which we propose to do".

UNIDENTIFIED DRUGS

SIR,—Patients often come to hospital with tablets which their general practitioners have been giving them for a long time, and the name of which they do not know. The houseman has to find out the name of the drug, and this often results in delay in treatment.

Would it not be better if the general practitioner told the hospital of any chronic illness in a patient referred for some acute condition, and the treatment that is being given? This would be a great help for the inexperienced junior members of the hospital staff, like myself.

PHYSICAL CHANGES IN THE PROLAPSED DISC

SIR,—Your annotation,[1] combined with Mr. Charnley's comments (July 5), has reminded me that we lack a basic philosophy which might illuminate our search for the cause of pain. The pathology of pain is ill-understood but accepted in general as pressure; therefore he who first propounds a plausible theory of pressure wins the honours.

But let us examine Mr. Charnley's invention of a suddenly expanded disc causing pressure like that in an abscess.

This is the ghost of turgor again,* and I thought that that had been laid fourteen years ago. Self-expansibility, said Ffrangcon Roberts,[2] is a quality unknown in physics: "to ascribe turgor or power of expansion to the nucleus is to invoke some property quite unknown in the physical world and takes Medicine back to the obscurantism of the Middle Ages".

Instead of turgor, Mr. Charnley calls it hydrophilia: dried discs swell when placed in water. Of course they do, as does any piece of dead cartilage. The disc is nothing but a resilient bit of fibrocartilage, more cartilaginous at its centre and more fibrous at its margin. Nucleus pulposus and annulus fibrosus are verbal expressions and not entities. Like other cartilaginous structures the disc cushions sudden or intermittent pressure by flattening, and it is restored to its previous shape when the compressing force is removed. Its resilience is shown by the rarity of disc lesions in compression fractures of the vertebral bodies.

Like other cartilage, the disc cannot have a weight-bearing function; continuous pressure causes its absorption or degeneration. The weight-bearing structures in the back are the pedicles and articular processes; narrowing of an intervertebral disc is always secondary to failure of these structures through decalcification.[3] Narrowing of the space, therefore, is not the cause of the pain but a later effect of the decalcifying process.

I am glad to read (1) that Mr. Charnley has never seen the actually swollen discs; (2) that protrusions are rare in acute lumbago; (3) that pain in acute lumbago is not proportional to the change in the disc. Could this not possibly mean that the disc is not the cause of the pain—that the pain, as elsewhere, arises in muscular, synovial, or ligamentous structures?

MICHAEL KELLY.

LEARNING TO LEARN

SIR,—The Students' Guide (Aug. 30) outlines present-day medical education in your usual lively manner. Especially interesting is your treatment of the faculty of learning. Teachers, absorbed in planning curricula, overlook that even more important than the science of teaching is this art of learning. Not all of us have to instruct, but we all need to assimilate, and we painfully rediscover what Hippocrates told us—that in a brief lifetime it takes a long while to learn. We get less from regular teachers than from irregular sources. How can we best acquire a habit of receptivity to unconventional means of knowledge? Of course, each of us must work out his private technique.

Learning does not deal with external knowledge alone; we have to revalue our own capacity for handling experience. In the past, many doctors changed over to a line of medicine different from that in which they began. What this means is that they fashioned their own curriculum later than the average. General practitioners sometimes became successful consultants, for the best of all reasons—they found that people wished to consult them. A young doctor today is not encouraged to change his course, but for any individual the start of true learning may be the moment he realises he had taken a wrong direction. Some advice from late beginners, who found a vocation through their own efforts and not from teachers, would be illuminating next year.

London, W.C.1.

HARLEY WILLIAMS.

GLUTETHIMIDE POISONING

SIR,—A patient with glutethimide poisoning has previously been reported from this hospital by one of us.[1] It was noted at that time that respiratory depression was very slight, that the condition responded to the administration of bemegride and amphenazole, and that the patient, during the period of coma, had attacks of laryngeal spasm closely resembling tetany. These attacks were exacerbated by the administration of bemegride. We have recently seen the identical features in another patient with glutethimide poisoning.

A married woman, aged 39, who had a long history of depression, was admitted to the Royal Victoria Infirmary on July 31, 1958, in deep coma. Three and a half hours before admission she had taken 22 tablets (5.5 g.) of glutethimide ('Doriden'). Her pupils were of normal size and failed to react to light, and the corneal reflexes were absent. The tendon jerks were depressed and the plantar responses were flexor. Respiration was not markedly depressed. Gastric lavage was performed and bemegride administered as a continuous intravenous infusion: in all, 850 mg. was given in two hours. The limb reflexes returned within thirty-five minutes and the corneal reflexes within three hours of starting bemegride.

Soon after admission intermittent attacks of spasm of the limbs, associated with tetanic spasm of the hands, were noted. Trousseau's and Chvostek's signs were negative, the serum calcium and phosphorus were normal, and intravenous calcium gluconate was without effect. Bemegride increased the spasms. The patient also had intermittent head retraction and attacks of laryngeal spasm. The muscles in spasm changed frequently, both flexor and extensor groups being involved intermittently and more independently in all four limbs. This resulted in an appearance in the upper limbs sometimes suggesting tetany and sometimes a posture reminiscent of [illegible]. The attacks of spasm decreased in severity and disappeared within fourteen hours.

The clinical features of this case were so similar to those of the previous one that we feel that there is an [illegible] that the attacks of muscle spasm were due to glutethimide. The site of action remains obscure, but, in view of the changing posture of the limbs, this may be in the corpus striatum

---

[1] [illegible] N. R. Lancet, [illegible]

This case underlines the safety of the therapeutic dose of glutethimide, and also that it is a suitable sedative for patients where respiratory depression should be avoided Bemegride is indicated in cases of poisoning

MIDGET ANÆSTHETIC MACHINES

SIR,—With reference to Dr Burton's letter last week, the universal adoption of the B S I pin index fitting for medical gas cylinders should facilitate the development of lightweight anæsthetic machines

We have had in use for six months an apparatus weighing 7 lb that can be fitted with any size of pin index cylinders The basis of the apparatus is combined cylinder yokes, regulators, and plastic flowmeters for the gases The fittings are standard anæsthetic equipment so that additions or replacements are easily available. A full range of gases can be used and any standard vaporising bottle included in the circuit. The similar heads for all sizes of the new cylinders together with the use of lightweight alloys in the machine allow the machine to serve in daily use and as a portable emergency apparatus

London, S W 3

J D K BURTON

THE PLACE OF THE RESEARCH INSTITUTE IN THE ADVANCE OF MEDICINE

SIR,—Sir Charles Harington's article[1] will have been read with great interest by medical research workers everywhere. As his closing theme he mentions the difficulty of establishing sufficient contact between the laboratory research institute and the sick patient, and considers the possible advantages of establishing institutes for clinical research.

Conditions in Malaya are very different from those in England, but this Institute for Medical Research has over a few decades achieved a fortunate blend of laboratory and clinical work.

The Institute itself has no beds, but is situated next to a large general hospital When a patient is admitted to the hospital with an illness known to be of interest to one of the Institute staff, we are notified, and, if after initial examinations the patient is deemed suitable for further research studies, the hospital physicians have generously allowed us to take over complete control of the patient while retaining the use of the hospital bed. This has been practised in the study of such diseases as beriberi, malaria, filariasis, and the nutritional anæmias

This happy state depends entirely upon the good will and confidence between the hospital and Institute staff at the personal level—a trust which has been built up for half a century

Such a system has the great advantage of flexibility, for when the study of any particular problem has been completed it is easy to pass to another by drawing upon a different type of patient in the large hospital pool

Many of the difficulties in tropical medical research are avoided by this efficient system, which allows maximum information to be gained from the material at hand. Experience here bears out Sir Charles Harington's view that such a combination of clinical and laboratory research can provide valuable results

Institute for Medical Research,

FERTILITY AND MENTAL ILLNESS

SIR,—In your leading article of Aug 16 you refer to a finding that "schizophrenics were as a whole about a quarter as fertile as the general population" It may be of interest to point out that Reiss and Hemphill[1] have shown that in many advanced schizophrenics there is vascular degeneration of the testes, this could undoubtedly have had an effect on the lowered fertility I have also noted the relation between hypothalamic disturbances and impaired fertility, and many men suffering from such conditions are infertile In two cases of narcolepsy there was severe infertility, and other observers have already noted this connection It may well be, therefore, that there is an organic basis to be taken into account as well as the "premorbid schizoid personality" making marriage less likely to which you refer

Manchester

BERNARD SANDLER

CARDIAC COMPLICATIONS OF COXSACKIE-VIRUS INFECTION

SIR,—We have already described[2] infection with Coxsackie virus type B4 as a cause of benign pericarditis Recently another of these cases has shown evidence of infection with Coxsackie virus type B3, and we would like to draw attention to the signs of cardiac involvement.

A man, aged 50, contracted an acute febrile illness which lasted for 5 days The onset was sudden with shivering, sharp pains in the chest, and considerable dyspnœa The initial temperature was 102 4°F There were crepitations over the lower lobe of the right lung, and pericardial friction was audible over the precordium, especially at the base of the heart. The heart rhythm was regular, rate 100 per min. X-ray of the chest on the day of admission showed moderate cardiac enlargement and an area of "ground-glass" consolidation in the lower lobe of the right lung An electrocardiograph at this time was abnormal, the T waves were negative in leads I, aVL, and V_{1-6}, with slight elevation of the S-T segments In association with the clinical findings these changes may be regarded as evidence of cardiac involvement with pericarditis Ten days later the electrocardiograph had reverted to normal, and repeat X-ray of the chest showed that the heart was now normal in size, and the consolidation of the right lung had resolved. Also the patient had made a complete clinical recovery

Results of neutralisation tests for Coxsackie virus type B in tissue culture (monkey kidney) carried out by the Virus Reference Laboratory, Colindale, London, were

Specimen	*Day of illness*	*B1*	*B2*	*B3*	*B4*	*B5*
1	9			1/80		
2	23	<1/10	<1/10	<1/80	<1/10	<1/10

Subsequent neutralisation tests over a period of three months showed titres of 1/64 for type B3 Routine laboratory investigations revealed no other significant features to account for the febrile illness white blood-cells 9450 per c.mm , anti-streptolysin titre positive 1/20 and negative 1/40, throat swab, *Streptococcus viridans* The patient's convalescence was uneventful, and recovery was complete

The neutralisation tests support the view that the patient had a Coxsackie-virus infection type B3 The acute febrile illness is typical of such an infection, especially the chest pains and pulmonary complications Cardiac involvement in Coxsackie-virus infection is becoming more widely recognised, and this case of type-B3 infection adds to the ætiological factors of benign pericarditis

HOW TO BE HAPPY THOUGH RESIDENT

SIR,—Hospital administrators will read with lively appreciation the homily addressed to residents by Mr Jennett, especially the reference to their relations with other departments of the hospital

At this hospital, and doubtless in many others, an invitation is extended to the residents, upon taking up their posts, to meet the chief administrative officer in an endeavour to start off on the right foot, when assurance is given of the fullest cooperation by the administrative staff

Although this is probably only practicable in medium-sized hospitals, experience shows that the simple gesture is usually appreciated

Wembley Hospital P E WINDO

DISSEMINATION OF MICROORGANISMS BY A SURGICAL PUMP

SIR,—The article by Mr Ranger and Dr O'Grady (Aug 9) revealed a possible, even likely, source of cross-infection in wards where mechanical suction is commonly used Their remarks relate to the Middlesex type of machine, and they recommend an effective remedy

This prompted a survey of all suction pumps in this group of hospitals, and the results of a few simple experiments show that we, at any rate, have been somewhat complacent

The group possesses two diathermy machines with suction pumps, five of Guy's Hospital type, three of Middlesex type, and two of uncertain breed The Middlesex machines are being dealt with as suggested by Mr. Ranger and Dr O'Grady and are now safe But the diathermy machines have no filter, and the exhaust is under the casing and discharges directly on to the floor The Guy's type are fitted with filters consisting of two felt discs which are secured to the back of the machine by a metal case of which the outer half is secured by two small, grub-like screws which are awkward to remove and worse to replace

The accompanying table shows the results of the admittedly primitive experiments

It is evident that there is a potential danger from suction pumps, even when provided with a filter, if the filtering material is not replaced after use in a septic case Ranger and O'Grady found that higher negative pressures produced more organisms at the outlet, but they refer to vacuums of 5–20 cm Hg The Guy's machine and the diathermy machines are designed to give up to 30 inches Hg! Possibly this is why surgeons seem to prefer them

RESULTS OF BACTERIAL CULTURES

Source	Type of machine	Culture
Theatre I	*Guy's* Inner disc Outer disc	*Staph albus*, *B subtilis*, *Bact aerogenes*, *Ps pyocyanea* *Staph albus*, non-hæmolytic streptococci, *Bact aerogenes*, *B subtilis*
Theatre II	*Guy's* Inner disc Outer disc	*B subtilis*, paracolon bacillus, hæmolytic anaerobic streptococci (group G) *B subtilis* paracolon bacillus
Theatre III	*Guy's* Inner disc Outer disc	*Bact alkaligenes*, *B subtilis* *B subtilis* only
Children's ward	*Guy's* Both discs	Coagulase-negative *Staph aureus* and an unidentified micrococcus
Neonatal ward	*Guy's* Inner disc Outer disc	*B subtilis* Sterile
Theatre I*	*Diathermy*	*Ps pyocyanea*
Theatre II*	*Diathermy*	*Staph albus* overgrown by *B subtilis*

* Obtained by holding a sterile celloidin membrane to the exhaust for three or four seconds

Splashing always occurs in the container when the cavity being drained empties, or when the machine is switched off, and some organisms are bound to be drawn into the pump, and are ejected when it is next switched on Contamination of the pump is naturally greater when suction is applied intermittently

The remedy, in the case of the Guy's type of machine, is to replace the small screws by a spring clip, which permits changing of the filter discs without tears The diathermy machines call for ingenuity in devising a trap which will not reduce the efficiency of the vacuum, probably enlarging the outlet hole, and leading a copper pipe to a trap attached to the machine, will meet most cases

Victoria Hospital,
Worksop, Notts GAVIN DUNLOP

FALSE GLYCOSURIA

SIR,—Bottles containing specimens of urine are brought to the general practitioner for testing When one uses the newer preparations for rapid testing for glucose, mistakes may arise when the bottle contains contaminants

Two specimens of urine brought to me in this way on successive days showed considerable glycosuria when tested by 'Testape' and 'Clinistix', but both specimens failed to reduce Benedict's solution

Both bottles had contained hydrogen peroxide, and, even though they had been washed before use, there was sufficient solution soaked in the screw cap to give a misleading result

Although this must be an uncommon incident, the fact that hydrogen peroxide may mimic glycosuria in the rapid test should be borne in mind to save an occasional patient from unnecessary concern

London, E 9 ALEC PHILLIPS

DIAGNOSIS OF SICKLE-CELL ANÆMIA AFTER BLOOD-TRANSFUSION

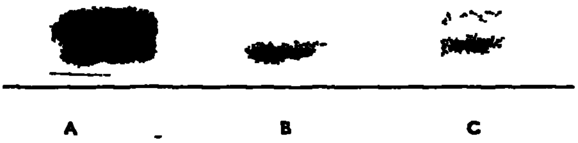
SIR,—Severe anæmia is commonly seen in the children's department at University College Hospital, Ibadan It is usually caused by malaria, malnutrition, or hookworm infestation or a combination of these, but it is quite often sickle-cell anæmia From time to time a severely anæmic child is admitted and transfused before appropriate investigations have been undertaken to establish the diagnosis of sickle-cell anæmia (The presence of the transfused normal erythrocytes in the patient's circulation interferes with interpretation of the hæmoglobin electrophoresis) Under these circumstances it has been our practice to defer hæmoglobin electrophoresis, to establish the diagnosis of sickle-cell anæmia, until the transfused cells have disappeared from the circulation—usually a period of 3 to 4 months The technique described below has recently been evolved in our departmental laboratory to obviate the time-lag in establishing the diagnosis

The erythrocytes of normal individuals are usually completely lysed in 0 3% sodium chloride solution,[1] whereas in sickle-cell anæmia lysis usually only commences in 0 34% sodium chloride and is often complete only in 0 01% sodium chloride[2] It is to be anticipated thus that lysis in 0 3% saline of blood obtained from a patient with sickle-cell anæmia after transfusion will result in destruction of all the normal cells,

---

1 Dacie, J V The Hæmolytic Anæmias London 1954
2 Diggs, L W, Bibb, J *J Amer med Ass* 1939, 112, 695

leaving intact only cells containing sickle hæmoglobin. A hæmoglobin solution prepared from the remaining cells would be expected to show only the abnormal hæmoglobin The



accompanying illustration shows the result of filter paper electrophoresis of different hæmoglobin solutions prepared from the blood of a patient with sickle-cell anæmia immediately after transfusion. Solution A was prepared by lysing all erythrocytes in distilled water Solution B was prepared from cells which resisted lysis in 0 3% saline Solution C is an A/S control It will be seen that while A shows an A/S pattern, B shows hæmoglobin S only

In sickle-cell/hæmoglobin-C disease and homozygous hæmoglobin-C disease the erythrocytes also show increased resistance to hypotonic saline solutions, and it is probable that these conditions could also be diagnosed with certainty in a recently transfused patient by employing this technique

Ibadan, Nigeria

R G HENDRICKSE

YOUTH CLUBS FOR THE HANDICAPPED

SIR,—Before retiring from the presidency of the Handicapped Children's Club, Bexleyheath, Kent, I should be grateful for the use of your columns to bring to notice the existence of this and similar organisations throughout the country

The Bexleyheath club started in March, 1954, under the auspices of the local Society for Mentally Handicapped Children and was reorganised in September, 1955, as an independent Handicapped Children's Club in order to cater for children with any type of mental or physical handicap At present there are 23 members (13 males and 10 females) and the majority are mentally defective (The remainder include spastics, educationally subnormal, and maladjusted children.) The age range is 10 to 33 years with mental ages of approximately 3 to 9 years Accommodation is provided in a local modern school and includes the use of a large hall, classrooms, garden, and playing-fields Play materials are obtained by purchase from club funds and gifts from supporters, in addition, the school authorities have kindly granted the use of equipment The regular staff consists of experienced and sympathetic voluntary workers, including 5 teachers from junior schools, 3 from occupation centres, and a few nursing and teaching students (the ratio of staff to members is roughly 1 to 3) Meetings take place fortnightly during the school term and are always well attended.

In April, 1956, an Independent Committee for Youth Clubs for the Handicapped was formed to promote the development of similar clubs in other areas A cine colour film, taken of the children's activities during the previous year, was shown in several districts of Kent and within 5 months a chain of clubs extended across North Kent The success of this venture encouraged the committee to show the film in London and the South-Eastern Counties, and by January, 1958, 17 new clubs had opened My latest information is that the campaign has spread to four other counties, 9 new clubs have been opened, and 17 districts are organising facilities

I feel these clubs fulfil a useful function in the socialisation and education of handicapped children, and they afford the parents an opportunity to enjoy regular and frequent contact, thereby reducing their sense of isolation The staff members, visiting speakers, and club library also help to dispel many misconceptions and old wives' tales concerning mentally handicapped children and thus alleviate much of the parents' self-blame and guilt In addition, the club serves a more general function in the promotion of mental health by acting as a focal point of local interest in mental handicap, where individuals and organisations interested in this work may congregate, and where visitors from all sections of the public are welcome

Further particulars regarding youth clubs for the handicapped may be obtained from Mr J B Millwood, hon secretary, 18, Martin Rise, Bexleyheath, Kent (telephone Bexleyheath 7331)

Clatterbridge Hospital,
Bebington,
Cheshire.

THE TREATMENT OF IDIOPATHIC THROMBOCYTOPENIC PURPURA

SIR,—Dr Watson-Williams and his colleagues (Aug 2) mention that they failed to find a recorded instance of a steroid-induced remission in a patient with a long history of purpura A case I reported of an Indian boy who developed purpura in 1949 and had a temporary remission after splenectomy[1] may therefore be of more interest than I suspected

In 1954 he was started on corticosteroid therapy and he has since been well controlled successively on cortisone, prednisone, prednisolone, and triamcinolone He has now had a continuous remission of twenty-three months to date this is certainly steroid-induced, for repeated attempts at reduction in his maintenance dosage of corticosteroids have resulted in prompt thrombocytopenia and bleeding gums Of the corticosteroids used in this case, triamcinolone has had the greatest therapeutic potency and has also been the most effective

Singapore

RONALD WELLS

STORAGE OF INULIN IN RENAL TISSUE

SIR,—According to most authors inulin is the ideal substance for the determination of the glomerular filtration-rate There is, however, in oliguric states a discrepancy between the clearances determined by the classical method and by the constant-infusion technique without collection of urine Part of the infused inulin must thus be metabolised and/or excreted extrarenally and/or deposited in the organism We have been interested in the storage of inulin in renal tissue

Having re-examined the fact that, in spite of a constant plasma-inulin level, the excreted quantity is well below the infused one, we found that there is about 1 17–4 03 mg of inulin per g of kidney substance This quantity, although significant, is too small to explain the difference between the infused and excreted amount during a clearance experiment of average duration

In another experiment dogs made oliguric by hæmorrhage were given an infusion of inulin The left kidney was then transplanted to the neck of a second dog, which was not given inulin The urine of the transplanted kidney, as well as the recipient's urine, was collected until free of inulin, and the whole excreted quantity of inulin determined The transplanted kidney was then analysed for the remaining inulin The sum of the three quantities was in fair agreement with the inulin content of the right kidney removed at the same time as the transplantation of the left kidney

The right kidney contained 1 03–5 75 mg inulin per g, the transplanted left one, having been "washed out" by the inulin-free blood and its own urine, contained only 0 22–1 84 mg per g (In 1 case we found 5 10 mg per g)

Our experiments seem to prove that some of the inulin infused can be stored in the kidney Part of this quantity seems to be in the dead space of the urinary tract, part of it in the renal vessels and interstitium There is, however, a small but significant quantity of inulin which remains stored in the renal tissue proper

---

[1] Wells, R *Proc Alumni Ass Malaya*, 1957, 10, 226

Nevertheless, this seems to be too small to explain the diminished clearance values in oliguria, and an extrarenal disposition of inulin has to be supposed

A detailed account of our data is to be published in *Acta physiologica hungarica*

Physiological Institute,
Medical University,

I FORGÁCS

"INCIDENCE" OF HYALINE MEMBRANE IN PREMATURE INFANTS

SIR,—We should like to call attention to a certain amount of confusion which exists with respect to estimates of the incidence of hyaline-membrane disease among premature infants Since there is no infallible method of establishing this diagnosis during life, it has been the usual practice to determine the presence of this condition from the microscopic appearance of the lungs at necropsy The incidence has then been computed as follows (hyaline membrane/total necropsied infants) × 100 = % incidence On the basis of these calculations those interested in this problem have been hard pressed to explain the high incidence of this condition among premature infants in the middle birthweight groups and the lower incidence among the lightest newborns

We have examined our experience over a 7-year period (1950–57) in the premature nursery of the Babies' Hospital During this interval 692 infants whose birthweight was less than 2001 g were admitted to the premature nursery following birth in the Sloane Hospital for Women, the intramural obstetrical service of the Columbia-Presbyterian Medical Center During the first three days of life 197 of these infants died Necropsies were performed on 150, and 86 were found to have hyaline membrane in the lungs

The "incidence" of this condition among these prematures is, of course, influenced markedly by the choice of a denominator population Since we were interested in determining the *influence of the degree of prematurity* upon the incidence of this condition, and since the mean age at death is later for large than for small premature infants, we calculated rates specific for birthweight and age at death, and they appear in the accompanying table

As can be seen the proportion of individuals examined at necropsy among those who died in the various age and birthweight categories was essentially the same Therefore, we have reckoned the "incidence" to be the number of examples of hyaline membrane at necropsy among the total number of infants admitted (less those who died in the previous age interval) For the purpose of this calculation we have made the assumption that the mortality-rate associated with hyaline-membrane disease was the same in the three birthweight categories

These estimates of the incidence of hyaline-membrane disease indicate that the condition occurs with equal or greater frequency among the lightest premature infants If these approximations prove to be related to the true incidence of hyaline-membrane disease, we may have nothing to explain except the factor of prematurity itself

"INCIDENCE" OF HYALINE MEMBRANE

Birthweight		≤ 1000 grammes	1001–1500 grammes	1501–2000 grammes
	No of infants admitted	116 infants	216 infants	360 infants
Died 0–23 hours	Died	56	33	20
	Necropsies	52	32	18
	Hyaline membrane	15	24	14
	% necropsied cases affected	(15/52) 29%	(24/32) 75%	(14/18) 78%
	'Incidence' in total population	(15/116) 13%	(24/216) 11%	(14/360) 4%
Died 24–47 hours	Died	22	21	21
	Necropsies	20	17	19
	Hyaline membrane	3	9	14
	% necropsied cases affected	(3/20) 15%	(9/17) 53%	(14/19) 74%
	"Incidence" in total population	(3/116–56) 5%	(9/216–33) 5%	(14/360–20) 4%
Died 48–71 hours	Died	9	8	7
	Necropsies	8	8	6
	Hyaline membrane	1	2	4
	% necropsied cases affected	(1/8) 13%	(2/8) 25%	(4/6) 67%
	"Incidence' in total population	(1/116–56–22) 3%	(2/216–33–21) 1%	(4/360–20–21) 1%

We suggest, speculatively, that other conditions associated with an increased incidence of hyaline-membrane disease (e g, maternal diabetes, cæsarean section, and placenta previa) may prove to be related only as the result of a common and unhappy association with prematurity

WILLIAM A SILVERMAN
Babies' Hospital, New York RUTH H SILVERMAN

GLOVES FOR NURSES

SIR,—The ineffectiveness of ordinary hand-washing is shown by the results of investigations on the bacteriology of the finger-tips of nurses

In these investigations, which have been carried out regularly here for nearly three years, each nurse, straight from duty in the wards, presses the tips of the unwashed index, middle, and ring fingers of the right hand on the surface of half a sterile blood-agar plate The nurse then washes her hands with toilet soap and hot water under a running tap, and dries *both her* hands on her individual sterile towel The washed and dried index, middle, and ring fingers of her right hand are then again pressed on the surface of the second half of the sterile blood-agar plate The blood-agar plate is incubated at 37°C for forty-eight hours and the colonies "before" and "after" are counted (1) after twenty-four hours' incubation, (2) after forty-eight hours' incubation, and the counts are recorded The plates are then kept covered for some weeks on the bench at room-temperature and examined from time to time for late developers Almost equal numbers of colonies develop in the "before" and "after" halves of the blood-agar plate

In another series of experiments, the procedure was the same except that "after" the nurse dipped her dried fingers into strong commercial methylated spirit up to the proximal phalanx for exactly sixty seconds The plate-counts "before" were unaltered, but the "after" counts were significantly altered—in fact, the "after" half of the plate was usually sterile More than a hundred experiments on these lines were carried out, with results that varied only slightly

We concluded that nurses should wear thin sterile rubber gloves when performing the following tasks washing and shaving a patient before operation; washing a patient after death and preparing the body, routine washing of a patient, passing a catheter and obtaining a sterile specimen of urine, changing the napkins of a baby and cleaning its bottom, changing wound dressings, giving a patient a bedpan or urinal, cleaning the patient and taking the bedpan or urinal to the sluice, and handling these objects while washing and sterilising them, if these operations are done by hand, changing stained bed linen, counting dirty linen (better to count the linen after laundering); giving streptomycin injections and filling the syringe, handling sputum pots, sputum jars, fæcal-specimen jars or pots, and swab-tubes, giving enemas, taking rectal swabs, manipulating colostomy tubes, and handling empyema and other drainage tubes Gloves also protect the skin of the nurse's hands from too frequent washing and drying

In the interval between any two tasks, and while performing a lengthy task, the nurse dips her gloved hands into a dilute disinfectant such as dilute watery chlorinated lime, chlorhexidine, or even tricresol, and dries her gloved hands on a sterile towel

In the absence of gloves, the conscientious nurse, following popular teaching, may find it necessary to wash and dry her hands more than a dozen times in a working day This repeated washing and drying is bound to injure the epidermis and cause the hands to become rough and dry and cracked This deterioration of the state of the skin is very serious, proper asepsis cannot be attained, and the nurse may develop a whitlow, which may incapacitate her for a week or more When her lesion has healed, and she returns to work, the repeated washing and drying of her hands will start her troubles all over again We are driven to the logical conclusion that the nurse should wear thin sterile rubber gloves, to prevent cross-infection and to protect her hands while at work

St. Margaret's Hospital,
Epping Essex.

FRANK MARSH

RESERPINE IN SCHIZOPHRENIA

SIR,—Although reserpine ('Serpasil') has now been used widely in the treatment of schizophrenia it might be of interest briefly to record the results of this treatment in a small mixed group of patients during the period May, 1956, to May, 1957

The 35 cases in this group consisted of insulin failures and relapses, or cases considered unsuitable for insulin therapy, thus, those with the best prognosis were excluded. Except that the patients were, in most cases, recent admissions, no other factors entered into their selection

At the start of treatment, dosage varied from 8 5 mg to 11 5 mg daily for about six weeks It was then gradually reduced, during the subsequent six to eight weeks, to 0 75 mg daily The duration of treatment varied from three or four months to a year, according to the duration of symptoms before treatment began and the willingness of the patient to cooperate after discharge from hospital To minimise the risk of a suicidal depression, relatives were advised in writing to inform their doctor if the patient should become depressed and the doctor was advised to inform us Most patients were discharged on trial for three to six months to give us further control of therapy Definite depression, a rare occurrence, indicated cessation of treatment.

After discharge from hospital, patients received routine visits from the psychiatric social worker and were followed up at the outpatient clinic at two to four weekly intervals While in hospital they had weekly interviews Supervision continued for an average of six months to a year

Patients were classified as "recovered" if they were fully socialised and revealed no overt psychotic manifestations, and as "relieved" if definite improvement rendered them capable of partial socialisation with marked diminution of psychotic symptoms The results were as follows

I Simple—2 cases of long duration Failed

II Hebephrenic—9 cases 4 recovered (2 cases were of over two years' duration and 2 of short duration) 3 relieved, 1 since relapsed (all over two years' duration) 2 failed (1 over two years and 1 probably over two) 6 (67%) recovered and relieved in all (omitting relapse)

III Paranoid.—19 cases 9 recovered (4 over two years, 5 of short duration) 3 relieved (1 relapsed since, all over two years) 7 failed (all over two years) 11 (58%) recovered and relieved in all (omitting relapse)

IV Catatonic.—3 cases 1 recovered (short duration) 2 failed (over two years)

V Puerperal—2 of brief duration 1 recovered, 1 relieved

In I, IV, and V the numbers were too small to be significant. From such a small group no definite conclusions could be drawn, but we would record our clinical impressions

(1) The cases most suitable for this form of therapy seem to be the colourless, apathetic type of hebephrenic We also noted that the paranoid patients most helped revealed a flattened affect, lack of colour, and spontaneity Patients with more colourful effect appeared to respond more satisfactorily to chlorpromazine.

(2) We feel it is important to continue serpasil in small doses, in cases of long duration, for upwards of a year, perhaps longer This appears to lessen the likelihood of relapse We had no case relapse while on maintenance treatment.

These comments are based on our hospital records up to June 30, 1958

S J KNOX.

Londonderry and Gransha Hospital,
Londonderry, Northern Ireland.

PRODUCTION OF LUNG CONSOLIDATION IN MICE BY STAPHYLOCOCCAL TOXINS

SIR,—Mice of mean body-weight 12 g, inoculated intranasally with a dose of from 0 1 to 1 2 mg of *Staphylococcus aureus* (Terajima strain) under light anæsthesia did not die, and only a slight congestion of the lungs, without abscess formation, was observed The inoculated organisms were gradually eliminated from the lungs within a few days But each mouse inoculated intranasally with 0 05 ml of a potent filtrate of the culture (prepared by the method described below) died with extensive hæmorrhagic consolidation of the lungs There was intensive congestion, œdema, and hæmorrhage but no abscess formation The filtrate plus the staphylococci produced extensive consolidation *with* abscess formation

Staphylococci were cultured in a semisolid agar (pH 7 2) consisting of 2% peptone, 0 2% agar, 0·3% NaCl, 0 2% potassium phosphate, and 0 03% magnesium sulphate, in an atmosphere of 20% CO_2 at 37°C for 48 hours The culture was centrifuged and the supernatant was filtered with Seitz EK to remove the organisms The activity of the cell-free filtrate was titrated and the titre expressed as the highest dilution causing complete hæmolysis of rabbit erythrocytes in a 0 5% suspension after 1 hour's incubation at 37°C Although the titre of the filtrate and the time till death of the inoculated mice was in an inverse relation, the limiting titre for cause of death was about 100

The following experiments were made with a filtrate with a titre of 1600 as a consolidation-producing dose which brought about death within 14 hours The power of producing consolidation and the hæmolytic activity of a filtrate were lost by heating at 60°C for 30 min., by treatment with formol (0 4‰, 1 week incubation), or by treatment with a sufficient amount of rabbit red cells at 0°C (indicating the adsorption of the active substances to the red cells) An antiserum prepared by immunising a rabbit with formolised filtrate neutralised the consolidation-producing toxicity in vitro These results suggest the presence of an intimate relation between alpha-hæmolysin[1] and consolidation-producing factor in the filtrate.

Each mouse was injected subcutaneously with a dose ranging from 100 to 500 µg. of tetraethylammonium bromide (T.E.A.), and 30 min later a consolidation-producing dose of a filtrate was given intranasally None of the mice died within 72 hours, and when killed they showed no consolidation. Each mouse of another group was injected subcutaneously with a dose ranging from 50 to 500 µg of chlorpromazine, and 30 min. later a consolidation-producing dose was given intranasally As in the case of T E A none of the mice died within 72 hours, and none showed pulmonary consolidation

---

[1] Glenny, A. T, Stevens, M F *J Path Bact* 1935, 40, 201

Penner and Klein [2] observed that direct contact of shiga neurotoxin and intestinal mucosa of dogs produced no lesion in the intestinal mucosa, whereas an intravenous injection of the toxin caused the appearance of a number of focal lesions, and that this phenomenon could be inhibited by injection of tetraethylammonium chloride

We [3-5] have reported that each particle of influenza virus (PR8), Newcastle disease virus, or hæmagglutinating virus of Japan can cause, even when infectivity has been destroyed, pulmonary consolidation in the inoculated mice, and that the production of consolidation is completely prevented by a previous injection of an adequate dose of T E A or chlorpromazine Since these drugs interfere with the passage of autonomic impulses through the central nervous system, it appears that staphylococcal toxins, like shiga neurotoxin or some viruses, have their primary action on the nervous system itself

SHOSHI TANAKA

SINGLE DAILY DOSE OF CHLORPROMAZINE

SIR,—In my letter [6] last March, I described a trial of treatment of patients on a single *daily* maintenance dose of chlorpromazine, and mentioned that other wards than the "pilot" ward had since followed up this idea with success

Further experience in these other wards shows that this success is only partial although the original pilot ward has carried on satisfactorily Of a total of 70 female patients on chlorpromazine in two large chronic refractory wards, where this method has been tried, it has proved possible to maintain satisfactory results in 32 patients only (45%) There were no real problems during the first weeks after the change to daily dose, but gradually it became necessary to change and divide the dosage because some patients were unduly drowsy during the day, because some patients appeared pallid and listless or complained of vague malaise, and because, as is often the case on these wards, individual patients' pattern of illness required changes in medication.

I thought it necessary to make this further report, in that this experience serves strongly to reaffirm the necessity of constantly regulating dosage to the individual needs of patients

TEXTBOOKS A NEW STYLE?

SIR,—The publication of a textbook in a cheap utility edition deserves your welcome (Aug 30, p 451), but it is no more than a hesitant step in the right direction The cheap edition referred to costs about 60% of the standard edition—itself an abbreviated 220 pages The suggestion that cheap textbooks could be obtained by limiting their contents does not solve the major problem The need is not for more short textbooks, but for cheap paper-back editions of the large standard textbooks

Few students can afford all the necessary textbooks at four or five guineas each We are further deterred from buying by the rapidity with which new editions appear, causing medical value, and financial value on the second-hand market, to depreciate alarmingly fast

It is clear that some subjects—for example, therapeutics—depending less on illustration are best suited to production on cheap paper But the Pelican books on art and architecture show that both photographs and line drawings can be adequately represented in cheap paper-back volumes Size should be no deterrent, if *War and Peace* can be published in two volumes for ten shillings, let a surgical textbook be published in three volumes for twice as much If the publisher, following Continental custom, produces a really cheap edition with the pages still stuck together, no matter, here at last is a sure way for the student to find out what parts of the syllabus he has not covered

S R MEADOW

THE GENERAL PRACTITIONER

SIR,—In his speech in the Lords' debate which you reported on July 12, Lord Moran spoke of a general decline in the status of the general practitioner

It began, he said, "when people generally felt when they were seriously ill that they were well advised to go into hospital That was extremely mortifying to the doctor He found that the patient, in this particular crisis in his life, preferred to put himself into the hands of a complete stranger" [1]

Unfortunately I have not kept statistical records, but on looking through my files I find that, in my five-and-a-half years in general practice, 116 of my patients have been content to die under my care, as against 15 who have died in hospital (3 of whom were admitted as surgical emergencies and 2 had no choice, being certified and carried off willy-nilly) This leaves aside two or three who made no decision either way, and were taken care of by the coroner, but it scarcely bears out Lord Moran's contention, unless one assumes that people who prefer to die in their own beds do not regard themselves as seriously ill

Admittedly many patients do go to hospital, but many return to their own doctor's care The visiting-list of a general practitioner which you published on July 5 should give pause to anyone who supposes that the illnesses of general practice are trivial or that the family doctor finds himself without heavy medical responsibilities

Kingston-on-Thames, Surrey

CHARLES STEER

HYPERTROPHIC PULMONARY OSTEOARTHROPATHY

SIR,—Mr Huckstep and Dr Bodkin (Aug 16) give an interesting account of the use of vagotomy to relieve painful hypertrophic pulmonary osteoarthropathy associated with bronchial carcinoma I should like to record a case in which relief was given by a simpler method

A man of 53 had bacteriologically proved pulmonary tuberculosis in 1955, for which segmental resection was performed A hilar glandular mass appeared seven months later, and at thoracotomy an undifferentiated squamous-cell carcinoma was removed

After another nine months he was readmitted with clubbing and fever, and painful œdema of hands and feet which had caused him to be bedridden for two weeks (No finger clubbing had been present after the first operation) As he appeared to have local recurrence of his growth, and hepatomegaly presumably due to metastasis, and as the condition of the extremities and fever were his only symptoms, he was started experimentally on a course of butazolidine, 200 mg twice daily, on May 5, 1957 This was gradually reduced to 100 mg daily The fever and œdema of hands and feet disappeared dramatically, although some clubbing of fingers and toes remained He was discharged home ambulant a month after starting the drug

Unfortunately he died at the end of 1957, but the painful œdema of the hands and feet did not recur while he was receiving butazolidine, which was continued for about four months in all

In cases of this kind it may be worth trying butazolidine before embarking on vagotomy

DIANA OWEN

HÆMOPHILIA-LIKE STATES IN GIRLS

SIR,—I read with great interest the article by Professor Quick and Miss Hussey in your issue of June 21, and I want to emphasise the following findings We, too, observed, with the late Prof E Frank, 2 cases of deficiency of antihæmophilic globulin (A H G) (thromboplastinogen) with prolonged bleeding-time

CASE 1 —A thirteen-year-old girl had an entirely negative family history In childhood she had prolonged bleeding after minor cuts and bruised easily She had severe epistaxis The laboratory findings are summarised in the accompanying table

Test	Case 1	Case 2	Normal
Bleeding-time (min.)	60	8–11	2
Coagulation-time (min)	12–25	11	8
Prothrombin-time (Quick) (sec.)	12	12	12
Prothrombin-consumption time (Quick) (sec)	10	15	34
Thromboplastin-generation test (Biggs-Douglas)	Abnormal	Abnormal	Normal
T G T with normal $BaSO_4$-treated plasma (sec.)	8	9	
Subject's $BaSO_4$-treated plasma substituted in the normal system	Abnormal	Abnormal	
A.H.G (%)	5	8	80–120

A H G -deficiency was noted, and A H G was 5% The case was a pseudohæmophilia B (vascular hæmophilia or angiohæmophilia A) The cause of the prolonged bleeding-time was investigated and a platelet defect was observed under the electron microscope The aggregation and adhesiveness, the formation of pseudopodia, and the spreading of hyalomere of platelets were absent or defective [1] [2] (see fig)

CASE 2 —A year later, a second similar case (an eleven-year-old boy) was observed and the platelet defect was noted under the electron microscope [3]

Defective pseudopodia formation and lack of spreading of hyalomere of platelet in a case of A.H G -deficiency with prolonged bleeding-time (×15,000)

These findings suggest that in vascular hæmophilia besides A H G -deficiency there is a platelet defect as in the thrombasthenia described by Braunsteiner [4] and by ourselves [5] In other words, these cases are combinations of thrombasthenia and hæmophilia (thrombasthenia hæmophilica) In these cases, the so-called Frank's athrombia [6] [7] does exist—that is to say, the bleeding-time is prolonged because of defects in the aggregation and adhesiveness of platelets The same defect of platelets has been observed by Paykoç and Erişilgil [8] in a case of Christmas disease with prolonged bleeding-time This finding confirms our observations

In my opinion, the third and fourth cases of Professor Quick are examples of the syndrome of thrombasthenia hæmophilica or athrombia hæmophilica

DIPLOMA OF CHILD HEALTH

SIR,—In your educational number (Aug 30) you do not include the Royal Faculty of Physicians and Surgeons of Glasgow amongst those bodies which grant a diploma of child health Reference to the advertisement pages of the same number will confirm that it does

Royal Hospital for Sick Children,
Glasgow, C 3

ROBERT A SHANKS

ACTION OF PSYCHOTROPIC DRUGS ON γ-AMINOBUTYRIC AND GLUTAMIC ACID IN RAT BRAIN

SIR,—Recently one of us (C de W) recorded [9] the results of an investigation into the inhibition of intermediary metabolism by some diphenhydramine derivatives Like the barbiturates, diphenhydramine reduces the oxygen consumption during oxidation of glucose (rat-brain slices) [10]

Generally speaking, the alkyl-substituted derivatives have a similar but more pronounced effect At the concentration used (0 002 M) the inhibition is antagonised by histamine Another remarkable effect is seen in the action of these compounds on aminoacid metabolism Paper chromatography showed that some of the compounds changed the level of at least two aminoacids which, to the best of our knowledge, were identified as glutamic acid and methionine Of the compounds investigated orphenadrine (β-dimethylaminoethyl 2-methylbenzhydrylether, 'Disipal'), gave the strongest effect—an elevenfold increase of glutamic acid and a more than seven-fold increase of "methionine" Orphenadrine, the pharmacological properties of which are quite different [11] from those of diphenhydramine, is used in the treatment of parkinsonism[12], but was recently found to have psychotropic activity[13] These observations suggested that it might be useful to investigate the influence of psychotropic drugs on the aminoacid metabolism

Using the "collidine" filter-paper technique of Dent [14] the influence of orphenadrine on the aminoacid spectrum was reinvestigated (substrate glucose 0 02 M, orphenadrine 0 002 M, buffer medium pH 7 2, weight of brain slices 80–100 mg) We were able to prove that the designation of one of the aminoacids mentioned above as "methionine" was incorrect, and that after the experiment γ-aminobutyric acid, as well as glutamic acid, was present in increased quantity

[12] Gillhespy R O, Ratcliffe, A H *Brit med J* 1955, ii, 352, Doshay, L J, Constable, K *J Amer med Ass* 1957, 163, 1352
[13] Scheurle, G *Dtsch med Wschr* 1957, 82, 2227
[14] Dent, C E *Biochem J* 1948, 43, 169

A preliminary investigation revealed that

(*a*) Psychotropic drugs inhibit oxygen consumption of metabolising brain slices from 0 to 89% (molar concentrations as above)

(*b*) If they affect aminoacid metabolism γ-aminobutyric acid and glutamic acid are involved, in some cases only glutamic acid is present in larger concentration after the experiment

The results so far are summarised in the accompanying table

INHIBITION OF OXYGEN CONSUMPTION AND INCREASE IN AMINOACIDS

Drug (0 002 M)	% inhibition	Aminoacid increase factor (normal value = 1)	
	O^{2} consumption	Glutamic acid	γ-aminobutyric acid
Chlorpromazine	89	7	10–20
Orphenadrine	59	7	10–20
Azacyclonol	36	4	1
Pipradrol	26	4	1
Benactyzine	25	3	1
Meprobamate	14	1	1
Adrenochrome (0 0005 M)	0	1	1
Deanol [15]	0	1	1

The inhibition of oxygen consumption by some psychotropic drugs is already known,[16] but it is not a specific property of these compounds As far as we know their influence on the aminoacid metabolism has not been investigated

During the past year γ-aminobutyric acid has attracted the attention of several investigators Its occurrence as free acid in relatively large amounts in the brain and its pharmacological actions—e g on central synapses—are very interesting [17]

We would not at the moment suggest that the action of some well-known psychotropic drugs could be explained by their influence on the γ-aminobutyric-acid and glutamic-acid level in the brain alone, but we think it useful to continue our investigations in this direction and into the possibility of a “ biochemical classification ” of psychotropic drugs

We are indebted to Mr W F Kafoe for his valuable help in the experiments

Public Health

Vaccination against Poliomyelitis

THE Minister of Health has issued details of the Government's plan for the extension of the poliomyelitis vaccination programme This plan, based on the recommendations of the Joint Committee on Poliomyelitis Vaccine, with Lord Cohen of Birkenhead as chairman, falls broadly into three phases

1 A drive to complete the vaccination of all those registered in the present priority groups and to raise the acceptance-rate among these groups as high as possible The present groups are (*a*) children aged 6 months to 15 years, (*b*) expectant mothers, (*c*) general practitioners, hospital staff in contact with poliomyelitis patients, ambulance staff, and the families of these groups

2 Vaccination of those born in 1933–42, thus raising the upper age limit from 15 to 25

3 Vaccination of a wider range of hospital staff—namely, all who come in contact with patients—and medical students and the families of these groups

4 Third injections It is suggested that these should be offered to all who have already had two, in approximately the same order in which they were given their earlier injections, and that an offer should be made as soon as possible to those who were vaccinated in 1956

Fluoridation

THE considered opinion of an international group of experts is given in a report from the World Health Organisation on the value of fluoridation of public water-supplies for the prevention of dental caries [1] This committee has no doubt about the efficacy, safety, or practicability of fluoridation it draws attention to the mass of evidence that concentrations of 1 p p m of fluorides, artificially or naturally present in drinking water, do no harm to health and go far to prevent decay of the teeth

Unfortunately many members of the public do not see fluoridation in terms of compensating for a deficiency they feel that something unnatural is being added, and they see possible danger to general health in drinking “ doctored ” water The importance of such opposition was shown recently by the local decision to discontinue fluoridation of the water-supply at Andover—one of the places which were participating in the Ministry of Health's test of the method At Andover, as in some towns in New Zealand, fluoridation had become an acute political issue, on which candidates in local elections were successful or defeated As the result of a series of elections, the scheme ceased to command a majority on the council and the original decision to cooperate was reversed [2]

The experience of New Zealand suggests that prejudiced opposition can be overcome by patient and vigorous instruction in the facts about fluoridation In a programme of this kind, publicity should be given to experiences of local natural fluoridation of public water-supplies, such as that at Deeping St James, in Kesteven, mentioned by the principal school medical officer for Lincolnshire in his annual report for 1957 In this area, the water has been naturally fluoridated at a constant level of 2 5 p p m for no less than twenty years, and, to quote the report, “ the markedly superior dental condition and oral hygiene of the children of Deeping St James provide striking evidence in favour of fluoridation of other water supplies ”

If the public could be convinced that countless people in these islands have been drinking naturally fluoridated water all their lives, with no ill effects, and that there is no essential difference between natural and artificial fluoridation, the opposition to this valuable preventive measure would at least be greatly weakened

Obituary

RUPERT WATERHOUSE

M.D. Lond., F.R.C.P.

Dr Rupert Waterhouse, for many years a leading Bath consultant with special interests in rheumatology and clinical pathology, died on Sept. 1 at the age of 85.

A Yorkshireman, he was born at Sheffield, the youngest son of John Hodgson Waterhouse, M.D. He was a descendant of Sir Gilbert Waterhouse, surgeon to Sheffield Royal Infirmary, and grandson of John Hodgson, who practised surgery in Birmingham. He was educated in Sheffield at the Collegiate School and at Wesley College, and studied medicine at St. Bartholomew's Hospital, qualifying in 1897. In 1[illegible] he settled in Bath, where he ultimately became physician to the Royal United Hospital and the Royal National Hospital for Rheumatic Diseases, and, as his consultant practice spread, he was invited in turn to become visiting physician to the Victoria Hospital, Frome, and the cottage hospitals at Chippenham and Trowbridge. He was elected F.R.C.P. in 1929. He was a founder and past president of the Bath Clinical Society.

He served in the 1914-18 war first as a combatant in the North Somerset Yeomanry and later with the R.A.M.C. in Gallipoli, Egypt, Palestine, and France, and for two years he commanded the South West Mounted Brigade Field Ambulance before being gazetted to command the [illegible]th Southern General Hospital. During the second world war he returned from retirement to take the place of the pathologist to the Royal United Hospital, who was on active service.

During his later years, immediately before he left active practice in 1945, he practised mainly as a consultant in clinical pathology. His description of the clinical entity of acute suprarenal insufficiency from bilateral adrenal hæmorrhage (*Lancet*, 1911, i, 577) is well known to clinicians as the Waterhouse-Friderichsen syndrome. Of his retirement L. H. writes:

"During his later years Waterhouse was much handicapped by deafness and by an increasing lameness associated with osteoarthritis and Paget's disease of the hip. In spite of these disabilities, he was never known to complain, he retained his dry sense of humour and often mordant wit until the end, and he will be remembered as one of the great physicians of Bath and perhaps the finest after-dinner speaker of his time in the West Country. He was always more interested in the art and science of medicine and in research than in building a large consultant practice. He stood for all that was honourable in the practice of medicine and was bitterly critical of any form of showmanship or self-advertisement. A great reader, he was also a very fine bridge-player and, despite his physical disabilities, continued to play until the end."

Dr Waterhouse leaves a widow, a son, and a daughter.

Appointments

CUSACK, NORA, M.B. N.U.I., D.C.H., D.P.H.: senior assistant M.O. and school M.O., Castleford and Normanton, Yorkshire.

EVERED, L. J., M.R.C.S., D.M.R.D.: part-time consultant radiologist, Mansfield area hospitals, Nottinghamshire.

JACKSON, AGNES, M.B. Aberd.: assistant M.O.H., Ross and Cromarty.

LEVEAUX, V. M., M.B. Lond., M.R.C.P.: part-time consultant physician, Derby group of hospitals.

SANDLER, MERTON, M.B. Manc., M.R.C.P.: consultant chemical pathologist, Bernhard Baron memorial research laboratories, Queen Charlotte's Maternity Hospital, London.

Notes and News

PREVENTIVE MEDICINE IN ANCIENT PERU

THE Incas were an extraordinary people, and it is interesting to have the account of preventive and curative medicine among them which Sir Weldon Dalrymple-Champneys wrote after his visit to Peru and gave as his presidential address to the Royal Society of Medicine's historical section.[1] He points out that "though the curative side of the picture can be more or less matched in other cultures, the preventive side . . . was in many ways in advance not only of other contemporary civilizations, but of all throughout the world up to the end of the nineteenth century."

The Inca empire lasted from about A.D. 1000 to the Spanish conquest.

The Inca State, Sir Weldon says, "was one of the most benevolent despotisms the world has ever seen, and certainly one of the most efficient. The State saw to it that every subject, whatever his age, ability or health, had sufficient housing, nourishment, clothing, and amusement . . . security in marriage, freedom of worship, protection from special industrial hazards, freedom from debt (there was no money), security from oppression (the Inca sovereigns never abused their power or allowed others to do so), and protection from enemies outside. All these benefits were theirs, provided that they were never idle during working periods, stayed in their own provinces except when going up to the capital, Cuzco, for a feast, and did not break the laws. The Incas, in fact, gave their subjects a moral code far in advance of the peoples surrounding them. . . ."

Though they had no written language, they had a method of recording statistics, and possibly certain simple facts.

"The instrument used to record such statistics was the famous *quipu* (or *quipo*), a cord from which hung numerous knotted strings of different colours, the position of the knots indicating units, tens, hundreds and thousands. Men were specially trained to make the quipus and to interpret them and they are believed to have recorded not merely statistics, but even historical events.

"A census of the whole population of the empire was carried out every year, the population being divided into age groups. The accuracy of these statistics was safeguarded by severe sanctions, for the keeper of the records (called the *quipu-camayu*) who did not know what he should know, or who lied, was punished with death, 'without hope of reprieve' and the Indian who ran away to escape the census was poisoned. Special envoys of the Inca called the people together for numbering, even when they were in *articulo mortis*.

"Though labour was compulsory, the sovereigns took care that it did not exceed the power of the individual, and for this purpose account was taken of age, sex, health and the nature of the work in question. Never were governors more careful of the health of their people." The mining of mercury, which gives rise to "tremors and nervous spasms", was forbidden, and so was fishing for pearls. Only a small number of Indians were sent to the coca plantations, situated in hot and unhealthy country, and these workers were always inhabitants of hot districts. For very laborious tasks there was a rota system.

"TEACH YOURSELF"

SINCE the Teach Yourself books were started some twenty years ago, about 300 have been issued, and their range of subjects is now astonishing. To celebrate the beginning of the 21st year there is now "A Concise Guide to Teach Yourself",[2] which in the words of Mr. Leonard Cutts, the editor, "is meant to introduce you, as agreeably as possible, to the infinite variety of knowledge, the endless things you could learn, and make, and do if life were only long enough."

In his foreword Mr. Ritchie Calder compares the series to the clandestine teaching movement, called "the Floating University", which flourished in Poland under the Czars. At any rate, he feels, the fact that the sale of these books runs into many millions suggests that "perhaps one is wrong in saying that we are becoming a nation of listeners-in and lookers-on." The authors include many whose names are widely respected, and Mr. Calder tells with relish the story of an undergraduate who scornfully rejected his advice to read one of the books—until he found that it was by his own professor.

SURVIVAL AFTER SHIPWRECK

In the world wars a high proportion of the deaths at sea were caused by drowning and exposure Between shipwreck and rescue survivors need buoyancy and nutrition, and details of experimental studies and of the equipment and procedures adopted by the Admiralty can now be seen on film

The Flotation Properties of Life-Jackets (16mm , silent, black-and-white, 12 minutes, Britain, 1945)[1] is a fascinating record of an investigation to discover whether a life-jacket lifted the head of an unconscious person out of the water Prof E A Pask, wearing a life-jacket, was anæsthetised by Sir Robert Macintosh and dropped repeatedly into a swimming-bath and a rough-water tank The efficacy of the jacket is well shown in the film from both above and below water at normal speed and in slow-motion

Survival at Sea (16mm , silent, black-and-white, 25 minutes, Britain, 1950–53)[2] shows a series of experiments conducted by the Department of Experimental Medicine, University of Cambridge, with various types of emergency rafts Investigations included conditions encountered in moderate, arctic, and tropical climates

Survival at Sea,[3] a recent film made by the Admiralty, shows in detail the equipment now used in the Royal Navy and the routine to be adopted by survivors Part I "Equipment" (16 and 35 mm , sound, black-and-white, 20 minutes, Britain, 1956) begins with a demonstration of the inflation and maintenance of a life-jacket, and then the inflatable life-raft and its associated survival-pack are described in detail The second half of the film is devoted to an exercise in which a raft is inflated and boarded The importance of maintaining body-fluid is emphasised, and accordingly fresh water and a plentiful supply of anti-seasickness tablets are provided Facilities for collecting rain water and a "solar still" are supplied Part II "Living on Air" (16 and 35 mm , sound, black-and-white, 32 minutes, Britain, 1957) is a dramatised account of life in a raft pending rescue Duties are allocated, and an inventory check showing the position of all the items in the raft and in the survival pack is carried out Boredom is relieved by a pack of cards and a comprehensive instruction book detailing the routine duties—times for issuing rations and so on Each man is given one pint of water daily to be drunk in the evening, next morning, and the remainder at midday Sufficient water for five days is provided, and as none should be consumed on the first day the survivors should be in good condition for six days Glucose sweets complete the rations The photography, all in sunny Mediterranean weather, is excellent

Royal Faculty of Physicians and Surgeons, Glasgow

On Aug 29 Prof Stanley Alstead, the president, conferred honorary fellowships on Sir Alexander Fleck, Sir Maurice Bloch, Prof Carl Browning, and Mrs Stirling of Keir

On Sept 1 the following were admitted to the fellowship

Sukumar Mukherjee, Raojabhai Ranchodbhai Patel, T F Rodger, George Rutledge, Thomas Symington

British Institute of Radiology

This institute will hold a meeting at 32, Welbeck Street, London, W 1, on Friday, Oct 17, when short papers on work in progress in radiobiology will be read

Committee on Artificial Insemination

The Government have now announced the names of the committee which, under the chairmanship of Lord Feversham, is to inquire into the practice of human artificial insemination and its legal consequences The members are

Dr L Priscilla FitzGibbon, anæsthetist to a group of Gloucestershire hospitals and a juvenile court magistrate, Mrs Peggy Jay, wife of Mr Douglas Jay, M P for Battersea North, and a member of London County Council, Dr D T McDonald, a general practitioner, Belford, Northumberland, Mr Ralph Risk, president of the Law Society of Scotland, 1957–58, Mr John Ross, formerly head of the Children's Department, Home Office, and chairman of the Marriage Guidance Training Board, Mr Justice Stevenson, Q C , a High Court judge, Dr R E Tunbridge, professor of medicine, University of Leeds, and Mrs H Whitley, wife of the minister of St. Giles' Catherdral, Edinburgh

The secretary of the committee is Mr R F D Shuffrey, Home Office, Whitehall, London, S W 1

University College, Ibadan

Mr W W Davey has been appointed to the chair of surgery

Mr Davey graduated M B from Queen's University, Belfast, in 1935, and after holding demonstratorships there in physiology and anatomy took the F R C S I in 1941 For the next five years he served with the R A F Medical Service, and he landed in Normandy on D-day with a surgical team In 1946 he was appointed chief surgical assistant to the gastroenterological unit at St James's Hospital, Balham In 1949 he took the F R C S , and the following year he took up his present consultant appointment as gastroenterological surgeon to Whittington Hospital and New End Hospital, London He gave a Hunterian lecture at the Royal College of Surgeons of England last year, and his published work includes papers on partial gastrectomy for peptic ulcer in the aged and on Rovsing's sign

Dr G M Edington has been appointed to the chair of pathology

Dr Edington graduated M B from the University of Glasgow in 1935, and after holding a resident appointment at Stobhill Hospital he joined the R A M C and served in India and Burma He was demobilised with the rank of major in 1946 and soon afterwards joined the Colonial Service He served at first as a pathologist in the Gold Coast (now Ghana), and in 1947 he took the D T M H In 1951 he took the D C P , and in 1953 he obtained his M D with high commendation The following year he was appointed specialist pathologist in charge of the medical research institute and laboratory services of the Gold Coast In 1957 he returned to this country to take up his present post of consultant pathologist to Whiston and Rainhill Hospitals in the Liverpool region This year he was appointed M B E in recognition of his services in Ghana. His published work includes papers on sickling and on abnormal hæmoglobin diseases

The Privy Council has recognised the clinical facilities at University College Hospital, Ibadan, for the purpose of the degrees of M B , B S , of the University of London for an initial period of three years

St Luke's Day Service

A service for doctors is to be held at All Souls' Church, Langham Place, London, W 1, at 11 A M on Sunday, Oct 19 Lord Moran and Sir Cecil Wakeley will read the lessons

Seats will be reserved for doctors and their families Application (stating the number of tickets required) should be made to the church secretary at All Souls' Church by Oct 16

Institute of Directors

This institute has set up a medical research unit to inquire into the health problems of directors The director in charge of the unit is Dr H Beric Wright, F R C S , formerly on the staff of the Shell Group

On Friday, Oct 3, at 3 P M , Prof Dorothy Russell will give the inaugural address to the Royal Free Hospital School of Medicine, Hunter Street, London, W C 1

On Monday, Oct 6, at 3 P M , Sir Christopher Hinton will give the inaugural address to the Westminster Medical School at Church House, Great Smith Street, London, S W 1

A conference of surgeons of the St John Ambulance Brigade will be held at the B M A House, London, W C 1, on Nov 1 and 2

Group-Captain H P R Smith has been appointed president of the central medical board and adviser in aviation physiology at the central medical establishment of the Royal Air Force

The Friends of Blandford Hospital have opened a fund to provide a memorial to the late Dr W H C Spooner at the hospital Donations should be sent to the treasurer, 6, West Street, Blandford

The Hand Club of Great Britain and the Second Hand Club are meeting at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2, on Saturday, Nov 22, from 10 A M Further particulars may be had from Mr H Graham Stack, hon secretary of the Second Hand Club, at 150, Harley Street, W 1

The annual dinner of the Sheffield Medical School Old Students' Association will be held in the Firth Hall of the university on Saturday, Oct 11, at 7 P M Further particulars may be had from Dr J D H Linfoot, department of pathology, Western Bank, Sheffield, 10

MALIGNANT DISEASE OF THE URINARY TRACT*

Sir Eric Riches
M.C, M S Lond, F.R C S
SURGEON AND UROLOGIST, THE MIDDLESEX HOSPITAL, LONDON, W 1

THE URETHRA

In the discussion of carcinoma of the bladder stress was laid on the different behaviour of papillary and solid growths In malignant growths of the urethra there is a similar duplicity of behaviour, but it depends more upon the situation of the tumour than on its histological structure

Seven years ago Cullen and I reported 34 cases of urethral carcinoma (Riches and Cullen 1951), to those I can now add another

The tumours fell into two groups, anterior and posterior, and there was evidence in some that the urethral growth was an implant from the bladder Invasion of the inguinal glands had occurred in half and distant metastases in about a third

Prognosis

There is a striking difference between the prognosis of the anterior and the posterior growths

Only 2 out of the 9 patients with growths of the anterior urethra lived for *less* than three years the remainder all passed the five-year mark Only 2 patients had metastases, and 1 of these, whose inguinal glands were irradiated, is alive and well seven years later By contrast, with tumours of the deep urethra the outlook is very bad 19 out of 20 patients were dead within four years and 14 had metastases

The increased liability to metastases is one of the reasons for the poor prognosis of deep tumours Other factors are the lateness of the symptoms and failure to recognise them at a curable stage In addition, the deep urethra is less accessible to treatment than the anterior part, and one may be reluctant to carry out a sufficiently radical extirpation for what appears to be a small localised tumour

Treatment

For anterior urethral cancer in the male the best treatment is partial amputation of the penis If radiotherapy is given in adequate dosage, the growth may be followed by stricture In women diathermy excision followed by irradiation, either by radium implantation or by X rays, is satisfactory In either sex suspicious glands in the groin should be subjected to biopsy, and, if invaded, treated by X rays or by block dissection

For the vulvourethral growths in women wide excision with urinary diversion offers some hope, but they are generally better treated by irradiation with radium needles or applicators Men with carcinoma of the bulbomembranous urethra often come too late for effective treatment. The story of a stricture, of periurethral and later perineal suppuration and of nodules in the skin with invaded inguinal glands, is characteristic Irradiation at this stage makes the infection worse but I believe that a combination of well-timed radiotherapy and of surgery is still our best weapon

Extension or implantation of a bladder growth into the urethra worsens the outlook it lays the inguinal glands open to invasion and it promotes distant metastases The urethral tumour may be discontinuous with the main growth, when it can be removed by a separate operation, but even a discrete papillary carcinoma of low malignancy will sometimes invade the inguinal glands It would appear that confinement to the narrow tubular urethra encourages growth into the deeper tissues, whilst in the more spacious bladder there is room for surface expansion

THE PENIS

Carcinoma of the penis is not common Of 24 patients with malignant penile growths the youngest was thirty-two and the oldest eighty-three The average age was sixty-one There were only 17 admissions to the Middlesex Hospital in five years

It is well known that the disease is exceedingly rare in those circumcised in infancy, and phimosis and its consequent lack of cleanliness are undoubtedly predisposing factors I do not advocate universal circumcision, but if the pædiatricians who condemn the operation saw some of the patients later in life they might reconsider their attitude

Types

Although it is one of the least malignant of the growths of the urinary tract, carcinoma of the penis obeys the rule and occurs in two main forms The *papillary* type grows slowly into a large cauliflower-like excrescence with surface ulceration Glands in the groin are enlarged by sepsis but rarely invaded by growth The total removal of the organ can be followed by cure The *ulcerative* type may be small, but it grows by infiltration of the underlying tissues, invasion of the inguinal glands, and sometimes by bloodborne spread through the cavernous spaces A man with this lesion may be dead within two years Thus, as in the bladder, the larger growths are often less malignant.

There are other types of which the intraepidermal carcinoma —known variously as Paget's disease, Bowen's disease, or erythroplasia of Queyrat—is considered to be precancerous At an early stage it can be cured by X-ray therapy leaving a presentable member

Treatment

Both surgery and irradiation have a part to play in treatment Irradiation alone, either by X rays or by radium, will sometimes cure a small lesion, but the need for amputation after irradiation arose in 5 out of 8 cases There is a natural desire to preserve the penis, and a patient may prefer a distorted member to none at all In 3 patients a local excision only was done, and 1 of them has survived five years without recurrence The other 2 are living after shorter periods The more usual surgical treatment is partial amputation, this was the choice in more than half the patients The need for total amputation is determined by the extent of the lesion, when the penis is almost completely destroyed, partial amputation is impossible I no longer do the radical amputation but prefer biopsy of the inguinal glands at the time of the total or partial amputation, dealing with them subsequently if necessary When the glands are invaded, irradiation should be the primary treatment,

---

* Based on the second of three Lettsomian lectures for 1958 delivered before the Medical Society of London

TABLE I—RESULTS OF TREATMENT IN CARCINOMA OF PENIS

5-year survivals	13/13 (*100%*)
10-year survivals	2/4 (*50%*)
Died from the disease	1 at 2 years*
Died from other causes, without recurrence	4 { 1 at 8 years 1 at 7 years 2 at 6 years

*Operated upon in 1954 and therefore not yet a possible 5-year survivor

but the need for a possible subsequent block dissection should be borne in mind

After treatment of the glands, by whatever method, there is a tendency to œdema of the legs This can persist for many months The ingenious rotation flap devised by Lee (1955) may overcome the tendency to non-union of the skin, but it adds considerably to the operation The other complication is meatal stenosis This occurs almost exclusively after partial amputation, and especially when irradiation has been given before operation It can be avoided by removing a disc of skin of the lower flap and by passing the urethra through this rather than through a stab wound A $^1/_2$-inch projection of urethra looks ugly at the time, but eventually it leaves a rosette of mucosa with no constriction

Cancer of the penis is the only carcinoma in the urinary tract which can boast a 100% five-year survival-rate (table I) (Savage 1957) Nevertheless, the 1 death in my series was from widespread pelvic deposits with compression of one ureter The ulcerative type can show its truly malignant nature

In partial amputation conservatism in the length of stump is desirable as sexual function may be preserved On the other hand, I believe that total amputation should include removal of the testicles

THE SCROTUM

Carcinoma of the scrotum is a dying disease which was formerly prevalent amongst chimney-sweeps, tar workers, gas workers, coalminers, and mule-spinners During 1936–39 only 4 cases were admitted to the Middlesex Hospital, and there have been none since

The primary growth should be treated by wide excision Invaded inguinal lymph-glands may be removed by block-dissection, followed if necessary by irradiation After irradiation the tissues in this region are devitalised and subsequent surgery is fraught with a grave danger of infection The danger appears greater in scrotal than in penile cancers, although it exists in both

THE PROSTATE

The prostate is the commonest site of malignant disease in the urinary tract and it accounts for about 10% of all cancers in men It is encountered in three main forms Firstly, there is the patient in whom the diagnosis is certain from the hard, irregular, fixed, infiltrating tumour felt on rectal examination Secondly, there is the latent or unsuspected carcinoma which has all the signs of benign hyperplasia but in which an area of carcinoma is found on histological examination after prostatectomy Thirdly, the occult form may be present in the patient who comes complaining of lumbago or sciatica without urinary symptoms He is often found to have widespread metastases

Diagnostic Aids

The serum-acid-phosphatase level is raised in some 80% of patients with metastases, and a figure of 10 King-Armstrong units is diagnostic of metastatic prostatic carcinoma With bone metastases the serum alkaline phosphatase is also raised, but this is not specific for prostatic tumours The administration of œstrogens will lower these figures if therefore the test is to be of help in diagnosis, blood must be taken before treatment is started

A prostatic biopsy can be performed by the transurethral route, with a needle through the perineum, or by open perineal excision Transrectal biopsy is also used in some centres A positive result is diagnostic, but in an early case it is difficult to remove the right nodule False negatives are not uncommon I have been somewhat disappointed by the results of immediate section at the time of operation, more than once the clinical impression of malignancy was more accurate than the histological picture given by rapid staining

The recent science of exfoliative cytology has also been used as a diagnostic aid In the examination of the fluid expressed by prostatic massage the experience of the pathologist is of paramount importance The diagnostic opinions of Prof J Bamforth, who has examined the secretion from many of my patients, have been of very great value Despite these modern aids, however, diagnosis still rests on the result of a careful rectal examination Early detection is the only way in which cases suitable for radical prostatectomy with a prospect of complete cure can be found

Treatment

Surgical

The theoretically ideal form of surgery is total prostatectomy, including removal of the prostatic capsule, the seminal vesicles, and the base of the bladder Because of early infiltration this ideal is attainable in only about 5–10% of cases In some American clinics a higher operability-rate is claimed, and this is used to encourage the routine annual rectal examination of all men over forty Whether this form of control will ever be accepted here is open to doubt

Radical prostatectomy can be done by the retropubic or the perineal route Its chief disadvantage is its liability to be followed by urinary incontinence its chief merit is a high potential cure-rate Kimborough (1956) reported the five-year survival of 36 out of 56 patients so treated

Simple prostatectomy by the retropubic, suprapubic, or perineal route will not completely remove the clinically manifest malignant prostate Sometimes digital removal of such glands is impossible, but usually they can be excised with diathermy For such cases, however, which almost break the surgeon's finger, transurethral resection offers a good alternative, provided the instrument can be introduced and provided enough tissue can be removed to relieve the obstruction For latent carcinomas open prostatectomy has the advantage over transurethral resection in that complete removal of the malignant areas is more likely Where there is reasonable doubt about the diagnosis I prefer the retropubic operation to transurethral resection A preliminary course of stilbœstrol sometimes makes the operation easier

The frequent origin of cancer in the posterior lobe or in the peripheral zone of the gland makes it imperative to remove the posterior capsule, rather than to enucleate the adenoma, in all prostatectomies After enucleation of a histologically benign adenoma recurrence as a prostatic carcinoma is not unknown I have records of 10 such cases

After enucleation of the gland I now excise the posterior capsule with the diathermy needle, the trigonectomy is continued downwards with the sheet of tissue covering the seminal vesicles The seminal vesicles are removed too if they are adherent This part is examined separately In a recent case the prostate showed benign hypertrophy, whilst the posterior lobe and its capsule contained infiltrating adenocarcinoma

Hormone Control

Stimulation of the prostate by androgens can be reduced by castration or by giving œstrogens Nesbit and Baum (1950) collected statistics of about a thousand cases treated by one or other method alone, and by the two together, comparing them with a control group of untreated patients The figures showed the longest survival in patients under the combined treatment with castration and œstrogens

Castration sounds abhorrent, but the operation is one of subcapsular orchidectomy which leaves something in the scrotum that is scarcely distinguishable from the atrophied testes resulting from œstrogens The patient is told that the operation will alter the secretion of the testicle It has many advantages for the man who cannot or will not take œstrogen or who forgets to do so It also allows a lower dosage with consequent lessened side-effects I believe that it should be an essential part of the treatment of every carcinoma of the prostate except in the latent cases with a small central area of cancer

Œstrogens act by inhibiting pituitary gonadotrophin which stimulates the testes It has been claimed recently that stilbœstrol has a local cytostatic effect as well, and in its phosphorylated form (' Honvan ') it is said to have an enhanced therapeutic action when given intravenously (Hasche-Klunder and Wilmanns 1957) In a trial on a few cases I have not found such an improvement, and the serum acid phosphatase has tended to rise rather than to fall, at least in the advanced cases ' Tace ', another proprietary œstrogen, is said to be stored in the fat and to give less troublesome side-effects

The initial dose of stilbœstrol may be as small as 3 mg a day, increasing to 15 mg a day, although Fergusson and Franks (1953) have shown that 100 mg is equally well tolerated and more effective I agree that this is so, but I prefer to withhold higher doses until a clinical failure to respond demands them. A maintenance dose is required indefinitely many patients have relapsed because the drug has been discontinued owing to an apparent " cure "

The common side-effects of stilbœstrol—testicular atrophy, impotence, breast changes—can be disquieting to the patient, but they are seldom severe enough to warrant discontinuance of treatment Of more serious import is the occasional case of fluid retention with œdema, some men with cardiac disease are forced to abandon the drug Again orchidectomy provides the alternative

Cortisone, which inhibits the production of adrenocorticotrophic hormone by the pituitary, has a place in treatment in some patients it will relieve the pain of bone metastases

Adrenalectomy and Hypophysectomy

Enlargement of the adrenals with an increased production of androgens may follow testicular atrophy, but the effects of bilateral adrenalectomy are not so dramatic as in carcinoma of the breast Scott (1956) states that it should be considered only if the patient has androgen metabolites in the urine whilst on a dose of 100 mg of cortisone daily

Methods of destruction of the pituitary by irradiation, ablation, or division of its stalk are on trial No large series of results has yet been reported

Irradiation

X-ray therapy was a useful ancillary method before the days of stilbœstrol and we are starting to use it again in patients with bony metastases Prostatic injections of radioactive colloidal gold have also been tried, but there is a danger of producing severe proctitis Most of the gold, moreover, escapes into the blood-stream during the first few minutes, into the urine during the first few hours, and into the lymphatics within the first few days (Kerr et al 1957)

Results

The prognosis of cancer of the prostate before the days of hormone control depended largely on its spread, on its degree of malignancy, and on the amount of urinary obstruction and renal damage it was causing In 1943 in a series of 70 patients treated by transurethral resection and X rays, I found an average duration of life in clinically manifest cases of nearly two years, 1 patient lived for five years In latent or unsuspected cases, treated by prostatectomy and X-ray therapy, the average survival was three years, 1 patient living for nearly ten years The advent of hormone control has brought about a remarkable change Although no patient can be said to have been completely cured, length of survival, relief of urinary obstruction, and the ability to lead an active life with freedom from pain are all greatly increased

I have not attempted to estimate percentage survivals the time from first symptoms to first treatment is too variable and the final follow-up not sufficiently complete I have, however, examined the records of 200 patients with a complete follow-up (table II), excluding those who had a malignant recurrence after simple prostatectomy The oldest patient was ninety-two, the youngest forty-five, their average age was sixty-eight 12 were over eighty when first seen

TABLE II—SURVIVAL IN 200 CASES OF CARCINOMA OF PROSTATE

Less than 1 year	40
More than 3 years	93
" " 4 "	75
" " 5 "	53
" " 7 "	31
" " 10 "	10

In considering the long survivors we must separate those who had a small central area of carcinoma in an otherwise benign prostate This was so in 3 of the ten-year survivors and 5 of those who lived for seven years

One man of seventy-three with such a latent growth developed a local recurrence in the prostatic urethra five years after prostatectomy For the next five years he took stilbœstrol, and he remained well until his death at eighty-three In several the growth was histologically of low-grade malignancy or of limited extent, but in some it was extensive One medical man had a hard fixed malignant prostate at the age of sixty-two Transurethral resection of 11 g prostatic tissue relieved his obstruction The gland showed extensive invasive adenocarcinoma He has had stilbœstrol, 5 mg daily, ever since, and he is alive and well twelve years later His serum acid phosphatase was never raised.

At the other end of the scale are the patients who have widespread osseous or lymphatic metastases when first seen, usually with a raised serum acid phosphatase There were 51 who had such metastases before treatment was started (table III) Multiple secondaries in the lungs

TABLE III—SURVIVAL IN 51 CASES OF CARCINOMA OF PROSTATE WITH METASTASES

Less than 1 year	11
More than 1 year	40

not infrequently disappear on treatment with œstrogens. *Bone metastases* regress more slowly and the changes are more apparent in the less common osteolytic deposits which may show recalcification Metastases in palpable lymph glands can disappear quite quickly As a rule a high serum acid phosphatase denotes a bad prognosis Its fall indicates a good response and new metastases produce a rise

Subcapsular orchidectomy was done in 68 of the 200 patients It is now our policy to use it more extensively Half the patients still alive and only a quarter of those who died had had orchidectomy The prognosis appears to be better in older patients, but I think the real explanation of this lies in a lower grade of malignancy The average survival of the 12 octogenarians was two years and four months

Conclusion

Prostatic carcinoma differs from the disease in other parts of the urinary tract in being influenced and controlled by naturally occurring hormones It is the first form of cancer to respond to treatment by oral medication, let us hope that there will soon be others

COMPARISON OF ANIMAL AND VEGETABLE FATS IN INCREASING BLOOD COAGULABILITY

G A McDONALD
M B Aberd
LECTURER IN MEDICINE

H W FULLERTON
M D Aberd , F R C P
REGIUS PROFESSOR OF MEDICINE
UNIVERSITY OF ABERDEEN

WE have shown previously that, after the ingestion of a meal of high animal-fat content, there occurs a shortening of the "accelerated clotting-time" (using plasma and Russell-viper venom) and of the clotting-time of whole blood in silicone-coated tubes (Fullerton et al 1953) An increase in coagulability after a high-fat meal has been found by other workers (O'Brien 1956, 1958, Keys et al 1957, Pilkington 1957) More recently, attempts have been made to determine whether this effect occurs equally after the ingestion of animal and vegetable fat Unfortunately, published reports have been conflicting, and a study of these reports does not provide an obvious explanation for the variation in results For example, O'Brien (1956), using the "accelerated clotting-time" *with Russell-viper venom and platelet-poor* plasma, found similar degrees of shortening after the ingestion of 50 g butter, 50 g margarine, and two eggs On the other hand, Maclagan and Billimoria (1956) found a shortening of the "venom-time" after ingestion of 2 oz butter, but not after the same amount of margarine In addition they found that the "calcium-times" (method of Biggs and Macfarlane 1953) agreed with the "venom-times"—shortening after feeding butter but not margarine

When these reports appeared we had already carried out a series of experiments which showed that ingestion of vegetable fat usually produced a shortening of the recalcified-plasma clotting-time of the same order as that which follows a meal of bacon, eggs, and butter In view of the discrepancy between the findings of O'Brien and those of Maclagan and Billimoria, we extended our experiments in the hope of finding the reason for their conflicting conclusions The issue appeared to us to be important since we have already adduced evidence to suggest that one factor related to the increasing incidence of cardiac infarction may be the increase in dietary fat (Fullerton 1955) Moreover the increase of dietary fat in this country in the past few decades has been due mainly to a greater intake of vegetable fat (Fullerton 1956)

Methods

All blood samples were obtained by dry-sterilised 5 ml syringes (all-glass 'Vim') and needles (19 B W G 1 in), separate syringes and needles being used for each blood sample Venepuncture was carried out as carefully as possible to reduce tissue trauma to a minimum, and a note was made if any difficulty was encountered in entering a vein 4 5 ml of blood was withdrawn and added to a tube containing 0 5 ml 1 34% sodium-oxalate solution The tube was inverted two or three times to ensure mixing and was then spun for 5 minutes at 2000 r p m The recalcified-plasma clotting (R P C) time was estimated by adding 0 2 ml *M*/50 calcium chloride solution to 0 2 ml of plasma in a glass tube (3 in x 3/8 in.) in a water-bath at 37°C The tube was gently tilted at intervals, and the end point was taken as the first definite appearance of fibrin threads All estimations were made in duplicate All the steps in this technique were undertaken by one of us (G A M), and the interval between withdrawal of blood and estimation of R P C time varied very little and was approximately half an hour

The method was found to give very consistent results The difference between duplicate readings in no instance exceeded 7 seconds, and averaged 2 2 seconds As a further check on the reliability of the technique, blood samples were obtained from veins at both elbows at the same time in 19 subjects Table I shows the results in 15 patients in whom no difficulty in venepuncture was encountered With 1 exception (case 1) the greatest difference between the two arms was 6 seconds In the other 4 subjects (see table II) difficulty in venepuncture at one elbow was unavoidable in the first two instances The R P C times on that side were 28 and 14 seconds less than on

TABLE II—SIMULTANEOUS R P C TIMES (SEC) IN BOTH ARMS (VENEPUNCTURE DIFFICULT IN RT ARM)

Rt arm	Lt arm	Difference
75	103	28
110	124	14
115	130	15
73	87	14
		Mean 17 8

the other In the remaining 2 subjects venepuncture at the right elbow was deliberately preceded by slight tissue trauma by the entering needle The R P C times on that side were 15 and 14 seconds less than on the other

The R.P C time was used as an index of blood coagulability in preference to the "accelerated clotting-time" using Russ viper venom and the clotting-time of whole blood in silico- coated tubes It has the advantage that no foreign throm plastin is added as in the venom test, and the techniq simpler than the use of silicone-coated tubes We have ever, found that all three methods show an acceleratio clotting during the phase of lipæmia after ingestion of a fat meal

Convalescent-ward patients, aged 20–61, with no hist cardiac disability, were selected as subjects After a samp venous blood had been obtained from the subjects in the f state, they ate one of the following meals

1 *Animal-fat breakfast* —2 eggs, 2½ oz bacon, 1–1½ oz bread, and tea with milk and sugar Fat content approximatel

2 *Vegetable-fat breakfast* —2 fishcakes fried in margarine with margarine, 1 oz walnuts (in shells), tea with milk and Fat content approximately 83 g (walnuts 14 6 g, mar 68 7 g)

The margarine used in the earlier experiments contained a amount of hydrogenated marine oil in addition to palm-kern palm-oil, and groundnut oil In later experiments we used a garine made specially for us which contained only coconut oi groundnut oil No significant difference in the results was when the type of margarine was changed The addition of wa to the vegetable-fat meal was made at the suggestion of the die who prepared it, she felt that patients would have had difficu consuming it if the total fat content had consisted of margarine

Blood samples were obtained at 3 and 4 hours after inge of the meal

Results

Table III summarises the results in 11 subjects wh one day took the high-fat meal containing bacon, but and eggs, and on another day the meal high in vegetable fat In general there is little difference between the readings at 3 and 4 hours In all 11 subjects the animal-fat meal was followed by significant shortening of the R P C time, at 3 hours this reduction varied from 28 to 66 seconds with a mean of 38 7 seconds, at 4 hours the range was from 24 to 73 seconds with a mean of 35 5 seconds No difficulty in venepuncture was encountered in this series of experiments

TABLE III—R P C TIMES (SEC) BEFORE AND AFTER HIGH-FAT MEAL

Subject	Animal fat			Vegetable fat		
	Fasting	3 hr	4 hr	Fasting	3 hr	4 hr

Means	114	75	79	118	82	88

After ingestion of the vegetable-fat meal, no significant shortening occurred in 1 subject (5), in this case difficulty was experienced in entering veins, and this may explain the unexpected result The reduction in another subject (6) was of doubtful significance (13 seconds) at 3 hours, and only 2 seconds at 4 hours, and there is no obvious explanation for this result In the other 9 subjects the reductions in the R.P C times were of the same order as those found after the high animal-fat meal, at 3 hours the range was from 23 to 57 seconds (mean 41 6 seconds), and for all 11 subjects the mean reduction was 35 6 seconds, at 4 hours the range was 19–69 seconds (mean 35 9 seconds), with a mean reduction for all 11 subjects of 29 7 seconds

These observations have been extended by measuring the R P C times in the fasting state and at 3 and 4 hours after 50 g and 30 g vegetable fat in 10 additional subjects The findings are presented in table IV In this series of experiments the special margarine referred to above (coconut oil and groundnut oil) was the only fat given At 3 hours after 50 g vegetable fat the reductions in R P C times varied from 10 to 46 seconds with a mean of 21 3 seconds, and at 4 hours the shortening of the R P C times showed a range of 3 to 32 seconds with a mean of 15 8 seconds When the fat intake was 30 g the mean reduction of R P C times was 11 6 seconds (range 6–21 seconds) at 3 hours and 15 1 seconds (range 2–34 seconds) at 4 hours Accordingly the reductions in R.P C times at 3 hours after the ingestion of vegetable fat are proportional to the amount ingested (intake 83 g, mean reduction 35 6 seconds, intake 50 g, mean reduction 21 3 seconds, intake 30 g, mean reduction 11 6 seconds), at 4 hours the difference between 50 and 30 g of fat is not significant

Discussion

The results demonstrate clearly that the R P C time shows a similar reduction after the ingestion of animal and vegetable fat when the amount ingested is approximately 85 g When the intake of vegetable fat is reduced the shortening of the R P C time is less pronounced In view of the discrepancies in the results of other workers we have paid particular attention to technique, and we are satisfied that, in our hands, the R P C test gives accurate and reproducible results if no difficulty in venepuncture is encountered We have been unable to discover a satisfactory explanation for the failure of some workers to find a shortening after the ingestion of vegetable fat

It seems reasonable to suggest that, since alimentary lipæmia accelerates the clotting of blood in vitro, it may lead to increased fibrin formation in vivo and so initiate and accelerate the development of atherosclerosis Our results show that, if this hypothesis is correct, animal and vegetable fats of the types used in our experiments are likely to have the same influence on the development of this process

Summary

The clotting-time of recalcified plasma is a satisfactory measure of the increase in coagulability following a high-fat meal if there is no difficulty in venepuncture

Equal amounts of the animal and vegetable fats used in our experiments produced approximately the same increase in coagulability

UNIVERSITY OF ABERDEEN

PREVIOUSLY we have adduced evidence which suggests that *one* factor which has a causal relationship to the increasing incidence of coronary atheroma and cardiac infarction may be the increase in dietary fat which has occurred over the past few decades (Fullerton et al 1953, Fullerton 1955, 1956) More recently we have shown that blood coagulability, measured by the recalcified plasma-clotting time (R P C), increases in approximately equal degree after the ingestion of animal fat (bacon, butter, and eggs) and vegetable fat (mainly margarine) (McDonald and Fullerton 1958) As Morris (1957) has pointed out, the increasing mortality from coronary-artery heart-disease has followed changes in vegetable-fat intake more closely than the alteration in animal-fat consumption, but he has stressed that epidemiological studies have failed to confirm the hypothesis of a single or simple dietary ætiology for ischæmic heart-disease We have already expressed a similar opinion (Fullerton 1956), and, in our view, attempts to explain the increasing incidence of coronary atheroma and cardiac infarction by reference to the single factor of greater fat consumption have confused the ætiological picture

Another trend which has been conspicuous in the past few decades has been the general decline of physical activity, largely owing to the increase in mechanisation of industry and in all forms of mechanical transport Morris et al (1953) advanced the hypothesis that men in physically active jobs have a lower incidence of coronary-artery heart-disease in middle age than men in physically inactive jobs, and pointed out that the disease is not so severe in physically active workers Further suggestive evidence has been provided by Brown et al (1957), who showed that among men in Birmingham aged 60-69 the prevalence of coronary-artery disease seemed to be unrelated to mental activity or smoking habits, but was fairly closely related to the physical demands of occupation, being highest for men in sedentary work Considerations such as these have prompted us to study the effect of physical activity on the increase in blood coagulability which follows ingestion of a high-fat meal

Methods

The experiments were carried out in healthy male medical students aged 20-27

" *Sedentary* " Day

On a weekday each student reported at the hospital at 8 30 A M, where, after a fasting venous-blood sample had been removed, he consumed a breakfast containing approximately 85 g fat ($2^1/_2$ oz bacon, 2 eggs, $1-1^1/_2$ oz butter, bread, and tea with milk and sugar) He reached hospital by private or public transport and the distance which had to be covered by walking did not exceed $^1/_2$ mile From 9 A M onwards he attended lectures and clinical instruction, walking approximately 200-300 yards in the intervals between them At 12 30 P M, $3^1/_2$ hours after completion of the breakfast, a second blood sample was obtained

TABLE I—R P C TIMES (SEC) FASTING (F) AND $3^1/_2$ HOURS AFTER 85 G FAT

Means	141 3	117 6	23 8	133 1	125 9	7 3

" *Active* " Day

On Saturday mornings the procedure adopted was exactly the same except that no classes were attended and each student observed the following schedule

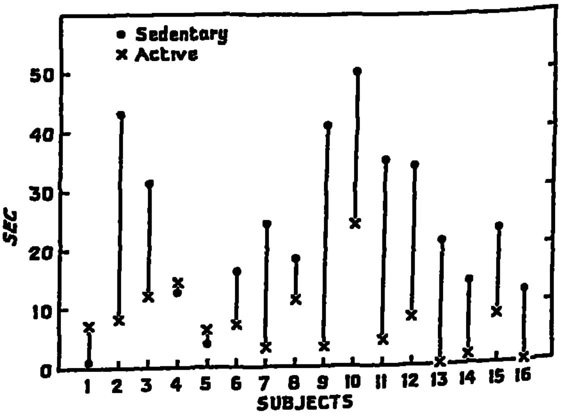
8 30-9 A M breakfast (fat content 85 g)
9-10 A M walking at a moderate pace for 3 miles
10-10 40 A M rest
10 40-11 40 A M walking for 3 miles
11 40-12 30 P M rest

Blood samples were again obtained before breakfast and $3^1/_2$ hours after it

In all cases coagulability was estimated by measuring the recalcified-plasma-clotting (R P C) time by the technique which we have described in a recent communication (McDonald and Fullerton, 1958) An alteration in the R P C time of 12 seconds or more has been regarded as significant

Results

23 subjects were observed on the " sedentary " day, and 16 of these on the " active " day as well The results in these 16 subjects are shown in table I and are represented diagrammatically in the accompanying figure 2 subjects (1 and 5), who showed no significant shortening of the R P C time at $3^1/_2$ hours while " sedentary ", are included in this group Because we were anxious to complete our observations before the start of a student vacation we later decided to observe, during the " active " day, only subjects who showed a significant reduction of



Reductions in R P C times $3^1/_2$ hours after 85 g fat

TABLE II—R P C TIMES (SEC) FASTING (F) AND 3½ HOURS AFTER 85 G FAT

Subject	Sedentary		
	F	3½ hr	Difference
17	146	136	10
18	124	124	0
19	147	140	7
20	139	134	5
21	129	126	3
22	135	123	12
23	132	128	4
Means	136 0	130 1	5 9

R P C time at 3½ hours while "sedentary" The findings in the remaining 7 subjects are shown in table II

Table I and the figure show that in all the subjects except 2 (1 and 5), the R P C time at 3½ hours was significantly shorter (difference 12 seconds or more) than the fasting reading while the subjects were "sedentary", the mean reduction for all 16 subjects being 23 8 seconds The results obtained when the subjects undertook the moderate exertion described above were strikingly different The mean reduction for all 16 subjects at 3½ hours was only 7 3 seconds Omitting subjects 1 and 5, it is seen that the significant shortening (difference 12 seconds or more) at 3½ hours in the "sedentary" phase is abolished in eleven subjects (2, 6–9, 11–16) and is much less in 2 (subjects 3 and 10) as a result of the moderate exercise Subject 4 showed a barely significant reduction at 3½ hours, of the same degree during both the "sedentary" and "active" phases In no instance was the reduction of R P C at 3½ hours significantly greater on the "active" day than on the "sedentary" day

The results obtained in "sedentary" medical students have been significantly different from those found in convalescent ward patients, aged 20–61, with no history of cardiac disability (McDonald and Fullerton 1958) These are presented in table III, arranged in two age-groups—20–24 and 30+ It is seen that (1) the fasting R P C time in the convalescent-ward patients is significantly lower in both age-groups than in the students, (2) the reductions in R P C time in the convalescent patients are greater for both age-groups than in "sedentary" students, and (3) a significant reduction in R.P C time occurred at 3 and 4 hours in all 11 convalescent patients, whereas a significant shortening was found at 3½ hours in only 14 of 23 "sedentary" students It is proposed to extend these observations, but it seems probable that even the small amount of physical activity undertaken by the students on the "sedentary" days may be sufficient to account for the longer fasting R.P C time, and the less conspicuous shortening of this time 3½ hours after the intake of 85 g fat The activity undertaken by convalescent ward patients is, of course, very little and entails walking only a few yards

Discussion

The hypothesis that the incidence of coronary-artery disease is inversely related to the general level of physical activity accords well with the findings presented above If shortening of the R P C time can be regarded as indicating a greater tendency to fibrin formation in vivo, and if intravascular fibrin formation is the important factor leading to atheroma, it follows that any factor which operates over long periods and which can be shown to shorten the R P C time is likely to be causally related to the development of atheroma In our opinion two of these factors are high intake of fat and low level of physical activity It is clear that other factors are important in regard to the development of coronary atheroma, as is evident from consideration of the sex distribution and the constitutional predisposition to the development of this lesion, but these cannot be held to account for the increasing incidence In many respects coronary-artery heart-disease seems to be a penalty which must be paid for a "higher standard of living" Many changes are involved when this standard is raised, in addition to an increase in dietary fat and a decrease of physical activity, but, since these two changes have been shown to increase blood coagulability, it seems reasonable to regard them as more important than factors of which have not been assessed in this objective manner If the development of atheroma depends on a long-continued process which favours fibrin formation without a concomitant increase of fibrinolysis, and if physical activity operates in the way we have suggested, it follows that a high general level of activity may well be important in preventing the development of atheroma, whereas phases of much physical activity at long intervals in a sedentary life are unlikely to delay significantly the progress of atheroma The business executive who undertakes little physical activity throughout the week is unlikely to compensate for this by playing several rounds of golf at the weekend

One factor in addition to physical activity which varied between the three groups of subjects studied was the degree of mental activity This could be regarded as moderate in the "sedentary" students, and negligible in students on the "active" day and in the convalescent patients The reduction in R P C time after the high-fat breakfast was greatest in convalescent patients, intermediate in "sedentary" students, and least in physically active students In other words it was inversely proportional to physical activity but was not directly correlated with mental activity It may be that the mental activity of the students on the "sedentary" days was insufficient to produce a distinct effect on coagulability, and further studies under conditions involving different degrees and types of mental activity might be rewarding

Summary

The acceleration of the recalcified-plasma-clotting (R.P C) time after the ingestion of 85 g fat was, to a large extent, abolished by moderate physical activity

The fasting R P C time was shorter, and its reduction after 85 g fat was greater in convalescent-ward patients than in "sedentary" students

NEPHROTIC SYNDROME AFTER THE APPLICATION OF MERCURY OINTMENT

N E WILLIAMS
M B Lpool
LATE HOUSE-PHYSICIAN

H G T BRIDGE
B M Oxon, M R C P
MEDICAL REGISTRAR

CLATTERBRIDGE GENERAL HOSPITAL, WIRRAL, CHESHIRE

FOR many years mercurial salts have had the reputation of being dangerous to nervous and renal tissue In 1948 Warkany and Hubbard warned against the risk of pink disease when calomel is given for teething troubles they showed that children with this disease excrete large amounts of mercury in the urine Bivings and Lewis (1948) confirmed the relationship and reported good response to dimercaprol (BAL) in 1 case Pink disease, however, may not be the only risk Wilson et al (1952) reported 5 cases of renal disease, which may have been caused by calomel, and Farquhar (1953) described an infant who developed pink disease at five months and fatal kidney damage a year later More recently Stoneman (1958) reported pink disease in siblings following the application of ung hydrarg ammon to the anal margins

Case-report

A lorry-driver, aged 52, was admitted to hospital in June, 1957, complaining of swelling of his ankles for a fortnight He had also noticed some breathlessness on effort and mild, gnawing, upper-abdominal pain after meals for a few weeks For over ten years he had suffered intermittently from psoriasis and he had been advised to rub in an ointment containing 5% ammoniated mercury, 15% tar, and 2% salicylic acid He had done this very regularly

On examination he had puffy eyelids and ankle œdema There was a psoriatic rash on his chest and limbs His urine contained albumin, 4 g per 100 ml There was no other abnormality his blood-pressure was 140/90 mm Hg. The serum-cholesterol was 650 mg per 100 ml, plasma-proteins 3 7 g per 100 ml (albumin, 1 3 g, globulin, 2 4 g), and blood-urea 26 mg per 100 ml The serum electrolytes, liver-function tests, chest X-ray, and barium meal were normal

The diagnosis of nephrotic syndrome was made and the patient was started on a high protein low-salt diet He was also given repeated double-strength plasma transfusions, acetazolamide, and katonium ion-exchange resin Despite this, his condition became worse his œdema rose to his thighs and sacrum, and he developed a small area of consolidation in one lung In view of this deterioration the diagnosis of mercurial poisoning was considered and the urinary excretion of mercury estimated This was 240 μg in twenty-four hours The patient was then started on a therapeutic trial of dimercaprol and the mercury excretion-test was repeated The twenty-four hour excretion was 640 μg on the fourth day of treatment and 1241 μg on the ninth day By the eighteenth day it had fallen to 84 μg From then onwards improvement was maintained Five months later the patient was completely well and the blood and urine findings were normal For safety's sake he was given a second course of dimercaprol

Conclusion

A patient developed a nephrotic-type illness following the application during many years of an ointment which contained ammoniated mercury, tar, and salicylate The high urinary excretion of mercury and the immediate clinical response to treatment with dimercaprol suggests that the cause of the illness was mercury poisoning The nervous system was not involved, and the renal changes were reversible

Because of the wide use of mercury salts the possibility of this complication is worth remembering

Our thanks are due to Dr R R Hughes, under whose care the patient was treated, and who made the diagnosis We should also like to thank Dr H G Farquhar for his help and Dr Hugh McLean, Dr Eve Patterson, and Mr R L Grainger for the laboratory estimations

TREATMENT OF INTERMITTENT CLAUDICATION WITH VITAMIN E

PETER D LIVINGSTONE
M B Edin, F R C S E
SENIOR REGISTRAR

CLIFFORD JONES
M B E, M B Lond, F R C S
CONSULTANT SURGEON

UNITED SHEFFIELD HOSPITALS

OPINION on the value of vitamin E in the treatment of peripheral vascular disease differs widely

Boyd et al (1949) reported favourably on its use in a series of 81 patients with intermittent claudication Boyd classifies these patients into three types type I are those in whom, on continuing walking or exercise, the pain disappears, type II are those in whom the pain attains a certain level and eventually the patient stops because of persistence of pain, and type III are those who stop because of its increasing severity He stated that all type-I cases obtained good results with vitamin E, in type II, 27 out of 72 obtained good results, 32 were improved, and 13 were unrelieved, whereas in type III the therapy had *no effect* This report, however, is open to criticism as the series did not appear to be adequately controlled

Baer and Heine (1949) threw doubt on the efficacy of the vitamin, and Hamilton and Wilson (1952) also reported unfavourable results, but in a very small series of cases Hamilton et al (1953) later reported a controlled series of 41 cases and expressed the opinion that vitamin E was of no value in the treatment of intermittent claudication This report has been criticised on the ground that the patients were treated for only twelve weeks

This discrepancy between different reports encouraged us to carry out a controlled experiment in a series of patients with intermittent claudication

Material

The series consisted of 40 non-diabetic male patients with obliterative vascular disease who complained of intermittent claudication *Males were selected for the ease of obtaining* adequate numbers, as well as to eliminate any possible sex difference in response

In all cases symptoms had been present *for at least* five years, and in all cases the pain was felt in the calf muscles 3 patients had had lumbar sympathectomy without lasting improvement All had received physiotherapy, and some had had grafts without lasting improvement

The average age of the control group was 57, and that of the vitamin-E group 55 9 There were 3 patients aged 40–50 in each group

Following Boyd's grading we found we had no cases of type I The distribution of the patients is shown in table I

Discussion

Any trial such as this is beset by many difficulties and possible sources of error Although we adopted the Boyd grading, in order to make some sort of classification, it seemed to us open to considerable criticism owing to the different reactions of patients to pain The time taken for pain to pass off varied widely in successive records, and this time was of little value in assessing our final results For example, several of the patients with poor exercise tolerance recovered remarkably quickly, and it can only be assumed that these patients anticipated the onset of pain and stopped before it became severe There was little difference between the ages of patients in the two groups, and each group included 3 cases of the younger age-groups

The average increase of 15 circuits in the group receiving vitamin E, compared with 2 5 in the control group, represents a considerable difference, which contrasts with the very slight increase noted by Hamilton et al (1953) These patients, of course, would show a much greater improvement when walking on level ground

As would be expected, cases of proximal thrombosis with a good collateral circulation benefited more than cases with extensive obliterative changes—although 2 cases of proximal thrombosis were included in our failures There was no significant improvement in the nutrition of the skin in any case

Six months after the end of the trial, of the treated patients who had improved none had deteriorated, and 3 patients in the control group who had been transferred to vitamin E at the end of the trial reported some improvement

Conclusion

Many criticisms can be applied to this study, but certain simple facts seem to emerge 13 of a final series of 17 patients on vitamin E improved, where as only 2 of a control group of 17 showed improvement In successful cases the patients are now carrying on their work with ease, and enjoying their leisure Apparently vitamin-E therapy does confer benefit in some cases

All these patients had undergone certain forms of therapy before undergoing this test, and had been disappointed with the results The fact that improvement was observed in most patients only after some months makes it unlikely that psychological factors played a part

It is well known that intermittent claudication will sometimes improve without any sort of treatment (Hamilton and Wilson 1952), but in our patients this explanation is unlikely because of the duration of their symptoms

We were unable to form any criteria which would enable us to select cases which would respond to vitamin-E therapy We confirmed Boyd's observations that large doses are necessary, and that treatment must be continued for a considerable period We also found that there is considerable delay before any response can be noted, and we concluded that therapy should be continued for at least three months before being abandoned

We owe a debt of gratitude to Roche Products for their help and cooperation throughout the trial, and particularly to Dr Margaret Briggs, their medical director

CORTISONE AS COVER FOR MAJOR SURGERY IN ADVANCED PULMONARY TUBERCULOSIS

J R Edge
M D Leeds, M R C P
PHYSICIAN, HIGH CARLEY HOSPITAL, ULVERSTON

PATIENTS who had collapsed with peripheral circulatory failure after major operations for advanced pulmonary tuberculosis were observed by me to improve remarkably after administration of cortisone (Edge 1956) There were no untoward effects on the residual tuberculous disease, and I suggested that such patients were suffering from adrenocortical deficiency

The present paper describes 17 patients with advanced pulmonary tuberculosis for whom major surgery was considered to offer the only real hope of permanently arresting the disease Each was a very poor surgical risk owing to the bad general condition, and the twenty-four-hour urinary 17-ketosteroid output before operation was found to be low in each case Replacement steroid therapy was given before, during, and after operation, in order to anticipate possible operative or postoperative collapse.

Clinical Material

There were 17 patients (14 male, 3 female), whose ages ranged from 26 to 58 (mean 45) The operations carried out were pneumonectomy in 5, lobectomy in 4, local excision of cavity in 1, and thoracoplasty in 7 The patients have been followed up for from six to twenty-one months after operation.

Extent of Disease

Chest radiography showed the number of zones involved to range from 3 to 6 (mean 5 1), the total cavity diameter ranged from 4 to 12 cm (mean 6 8 cm)

Sputum Status

The sputum of all 17 patients on admission to hospital contained tubercle bacilli on smear, and 12 remained sputum-positive up to the time of operation The remaining 5 became sputum-negative between two and four months before operation A significant level of bacterial resistance was demonstrated in 10 patients, in 3 the organisms were shown to be fully sensitive, whilst in 4 no information is available

Urinary Excretion of 17-Ketosteroids

Twenty-four-hour urinary excretion of 17-ketosteroids was measured by the modified Callow-Zimmerman technique (Dyke 1951) In the 3 women excretion ranged from 1 5 to 4 2 mg per twenty-four hours (mean 3 2 mg) (mean normal value in females, 9 mg per twenty-four hours), and in the 14 men from 2 8 to 8 9 mg per twenty-four hours (mean 6 7 mg) (mean normal value in males, 15 mg)

The twenty-four-hour 17-ketosteroid excretion was also measured in 10 men (aged 24–58, mean 41) all of whom had pulmonary tuberculosis of more limited extent, which was responding satisfactorily to antibacterial treatment alone, and all of whom were in very good general condition In these patients the values were higher than in those with advanced disease, ranging from 8 8 to 18 0 mg daily (mean 13 0 mg) These figures correspond with those cited by Dyke (9–23 mg [mean 15 mg] per twenty-four hours) as normal for males

Replacement Cortisone

When the resting urinary twenty-four-hour 17-ketosteroid excretion was found to be low, cortisone by mouth was started three days before operation in a daily dosage of 100 mg (25 mg six-hourly), this was continued for a week after operation, and then reduced in weekly steps of 25 mg to 75, 50, and 25 mg daily The total duration of treatment was four weeks

Postoperative Course

Mortality

There were three postoperative deaths 1 patient died a week after operation from uræmia due to renal amyloid disease, the 2nd died suddenly, on the third day after pneumonectomy, from spontaneous pneumothorax on the good side, and the 3rd, who carried organisms highly resistant to streptomycin, isoniazid, and *p*-aminosalicylic acid, died of bronchopleural fistula ten weeks after operation

Complications

The remaining 14 had no postoperative complications, apart from transient basal collapse in 1 instance The postoperative course was remarkably free of incident, the patients remained free of fever, dyspnœa, hypotension, and tachycardia and on the day after operation looked and felt none the worse for the operation The pink colour and lack of any suggestion of dehydration were particularly striking Wound healing proceeded quite normally in all cases

Late Results

2 patients have a persistent cavity with consistently positive sputum at nine and twelve months after thoracoplasty, 1 showing total and one partial bacterial resistance 2 patients remained culture-positive for three and six months after thoracoplasty, but have been since negative up to fifteen and twenty months respectively The other 10 patients, followed for from six to twenty-one months after operation, have remained radiographically and clinically satisfactory with consistently negative sputum on smear and culture

Discussion

Steroid hormones have been shown to be of value in the preparation and management of patients undergoing major surgery, apparently acting in one of three ways (1) by replacing a known deficiency of endogenous steroids in conditions such as Addison's disease and pituitary failure (Troen and Rynearson 1956), (2) by correcting a presumed adrenocortical deficiency in malignant and other wasting diseases (Ruddell and McKeown 1956, Szilagyi et al 1952, Cole et al 1953), or (3) by suppressing the disease process in conditions such as ulcerative colitis and hæmolytic anæmia, thus affording an opportunity for surgical treatment (Abbott et al 1955)

It has been shown by Forbes et al (1947) that patients with various chronic debilitating diseases (though not including tuberculosis) commonly have a low excretion of 17-ketosteroids in the urine, these patients do not respond to medical or surgical insults by an increase in steroid output, as do normal people (Sandberg et al 1954) In corollary, several workers have pointed out the greatly increased risk of surgery in patients whose adrenal function had been suppressed by steroid therapy, and in whom replacement had not been continued over the operative period (Hayes 1956, Allanby 1957, Slaney and Brooke 1957), while Popert and Davis (1958) found no increased liability to postoperative complications in a group of patients whose long-term steroid treatment was continued over the operative period

Earlier fears of activating any tuberculous infection present appear to be ill founded, provided adequate antibacterial treatment is also given (Houghton 1954) In the present series the giving of cortisone for four weeks to 10 patients with resistant organisms was followed by bronchopleural fistula in only 1 instance, thus might have been expected in any case in view of the high level of resistance present

With the increasing use of long-term chemotherapy, major surgery for pulmonary tuberculosis is being increasingly reserved for patients with far-advanced disease in whom chemotherapy alone is inadequate Many such patients present a formidable, and sometimes prohibitive, surgical risk

The operative mortality (18%) in the present series was certainly no higher than might have been expected bearing in mind the nature of the clinical material, in each case death was directly due to a definitive complication unrelated to stress The equanimity with which the remaining patients tolerated the stress of operation was remarkable

The present study suggests that it would be useful further to investigate adrenal function in patients debilitated by tuberculosis or other chronic illness who require major surgery, with a view to replacing adrenal steroids where these are found to be deficient

Summary

17 patients with far-advanced pulmonary tuberculosis, in very poor general condition, were submitted to major surgery Each had a low twenty-four-hour urinary 17-ketosteroid excretion before operation, and the operative period was covered by oral administration of cortisone

There were 3 postoperative deaths from definitive complications unrelated to stress The remaining patients tolerated operation well It is suggested that the replacement of deficient endogenous adrenal secretion contributed substantially to their recovery

My thanks are due to Mr J S Glennie and Mr P Jewsbury, who operated on the patients, and to Dr J E Horrocks and his staff who carried out the urinary 17-ketosteroid estimations The expenses of this work were defrayed by a grant from the Research subcommittee of the Manchester Regional Hospital Board.

" the scholar is in duty bound to remain unconvinced except upon the most solid assurances, and no one is a whit the worse for his indecision Now compare his situation with ours, where sick, frightened folk look to us eagerly for treatment, advice, and reassurance The scholarly fellow who says 'It may be so and so, but the evidence is incomplete', has little to offer to the sick in body and mind We are here in a domain more pristine than that of reason, a territory where symbols possess immense power. Some of us in our modern wisdoms run a danger of losing touch with the fears of our patients We sneer at their dependence on the bottle of medicine, and say they must be weaned from their fanciful attachment In situations—and they are frequent—in which we are relatively helpless, the bottle of medicine is often the most potent and most economical psychotherapy There are signs that some patients are being weaned from the bottle—to what? In place of the simple bottle we have to substitute the hypodermic syringe, the psychotherapist, the X-ray apparatus, the physiotherapy department "—Dr R E HOPE SIMPSON, *J Coll gen Practrs*, August, 1958, p 225

URINARY δ-AMINOLÆVULIC ACID AND PORPHOBILINOGEN IN DIFFERENT TYPES OF PORPHYRIA

Birgitta Haeger
M D Lund
From the Departments of Clinical Chemistry and Medicine (University of Lund), General Hospital, Malmö, Sweden

During attacks of acute intermittent porphyria (A I P) increased amounts of porphobilinogen are regularly excreted in the urine Waldenstrom (1937) found that in families with A I P several siblings excreted porphobilinogen in the urine without showing symptoms of porphyria Such cases were regarded as latent A few persons who had had attacks of typical acute porphyria did not excrete porphobilinogen in their urine when investigated by the methods then available The question thus arose whether the presence of some earlier porphyrin-precursor in the urine might not be a more reliable criterion of the porphyria-carrier trait

Recently Mauzerall and Granick (1956) devised a more sensitive method for quantitative determination of porphobilinogen than that described by Vahlquist (1939) They found that the precursor of porphobilinogen, δ-aminolævulic acid, was also present in large amounts in the urine of 2 patients with acute porphyria, and they devised a method for quantitative determination of this substance Small amounts of δ-aminolævulic acid (ALA) as well as porphobilinogen (PBG) were found even in normal urine

Material and Methods

Quantitative determinations by the method of Mauzerall and Granick (1956) were made of δ-aminolævulic acid and porphobilinogen in urine from 50 healthy adults, 50 healthy children (aged from seven months to fourteen years), 34 patients with A I P, and 128 of their closest relatives, as well as from 12 patients with porphyria cutanea tarda It was not always possible to obtain twenty-four-hour samples therefore the results are given in mg per 100 ml

At first determinations of the uro- and copro-porphyrins were made semiquantitatively by the method used by Waldenström (1937) Spectral analyses were made of the acid extracts in a Baly cuvette The following scale was used

Thickness of layer—>20 mm = negative 20–15 mm =(+) 15–8 mm =+ 8–1 mm =++—<1 mm =+++

Later the uroporphyrin was determined quantitatively according to Askevold (1951) and calculated according to Rimington and Sveinsson (1950) with corrected factor according to With (1955) As early as 1939 Waldenström and Vahlquist emphasised, however, that quantitative determination of uroporphyrin in acute porphyria is of little value, since porphobilinogen is readily converted to uroporphyrin

Coproporphyrin was determined by Askevold's modification (1951) of Fischer's original method, with the exception that the last washing was done with a fresh aqueous 1/200 dilution of a 1% solution of iodide in alcohol according to Schwartz, Zieve, and Watson (1951) with calculation according to Rimington and Sveinsson (1950) and corrected factor according to With (1955)

Results

Normal Values

The values of urinary δ-aminolævulic acid and porphobilinogen in 50 healthy adults and 50 healthy children are given in table I

To exclude errors due to varying concentrations of urine, in the latter part of the investigation the urinary excretion of δ-aminolævulic acid and porphobilinogen was calculated in relation to the excretion of creatinine Table II shows the normal values when calculated in this way

TABLE I—NORMAL URINARY CONTENT OF δ-AMINOLÆVULIC ACID AND PORPHOBILINOGEN

	δ-aminolævulic acid (mg per 100 ml)		Porphobilinogen (mg per 100 ml)	
Adults	M–0 305	S D–0 133	M–0 105	S D–0 046
Children below 15 years	M–0 257	S D–0 115	M–0 047	S D–0 031

TABLE II—NORMAL URINARY CONTENT OF δ-AMINOLÆVULIC ACID AND PORPHOBILINOGEN

	δ-aminolævulic acid (mg per g creatinine)		Porphobilinogen (mg per g creatinine)	
Adults	M–1 9	S D–0 6	M–0 7	S D–0 4
Children below 15 years	M–3 7	S D–1 4	M–0 6	S D–0 3

Normal urinary content of uroporphyrin
Semiquantitative method negative
Quantitative method 0–15 µg per l (25 healthy adults)

Normal urinary content of coproporphyrin
Semiquantitative method (+)
Quantitative method 0–175 µg per l (50 healthy adults)

Patients with Acute Intermittent Porphyria and their Relatives

The results of the analyses in the different groups are shown in table III and figs 1–3

Of 45 persons in group 3, 10 (22%) had latent porphyria The siblings examined were from 23 different families with 37 known cases of manifest A I P This brings the frequency of latent and manifest porphyria up to

TABLE III—ACUTE INTERMITTENT PORPHYRIA

Group	No of cases	Normal excretion of ALA and PBG	Pathological excretion of ALA and PBG	Pathological excretion of ALA only	Pathological excretion of PBG only
1 Acute manifest intermittent porphyria	34	0	29	0	5
2 Offsprings of patients with latent or manifest porphyria					
<15 years	31	21	1	0	9
>15 years	24	18	1	0	5
3 Siblings of patients with latent or manifest porphyria	45	35	7	0	3
4 Nephews and nieces of patients with latent or manifest porphyria					
<15 years	12	12	0	0	0
>15 years	9	9	0	0	0
5 Apparently healthy parents (but genetically certain carriers of the porphyria trait) of patients with latent or manifest porphyria	7	0	6	0	1
Total	162	95	44	0	23

ALA = δ aminolævulic acid PBG = porphobilinogen

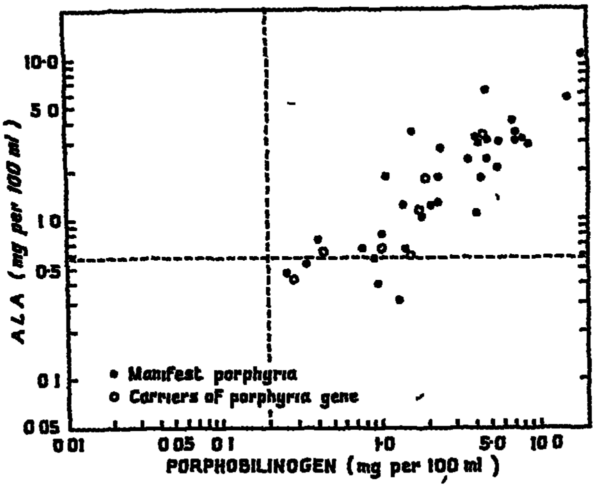

Fig 1—ALA and porphobilinogen urinary excretion of 34 patients with manifest porphyria and of 7 genetically certain carriers of the porphyria trait The line parallel to the ordinate corresponds to M+2S D mg porphobilinogen per 100 ml, the line parallel to the abscissa to M+2S D mg ALA per 100 ml Logarithmic scale

57% The value must be somewhat too high, but it does support the widely accepted assumption (Waldenstrom 1937, 1956 and others) that the trait of A I P is inherited as a simple dominant factor

If a person's child and one of his parents, or a brother or sister, or a nephew or niece had latent or manifest A I P, he was said to be a genetically certain carrier of the porphyria trait Urine was obtained from 7 subjects satisfying these criteria These carriers, who had never had symptoms of A I P, were between thirty-seven and seventy-one years In 6 the excretion of δ-aminolævulic acid as well as of porphobilinogen was increased, in the 7th the porphobilinogen only was raised Thus the values were pathologically increased in all of them (fig 1) This shows that latent porphyria can remain latent even in the older age-groups It also suggests that the disease can be transmitted only by persons with latent or manifest A I P This assumption is strengthened by the observations made in group 4, where neither the δ-aminolævulic acid nor the porphobilinogen levels were increased in the urines of offsprings of healthy siblings of patients with A I P

Patients with Porphyria Cutanea Tarda

According to Waldenstrom (1957) this heterogenous group can be divided into at least two subgroups—porphyria cutanea tarda symptomatica, and porphyria cutanea tarda hereditaria or protocoproporphyria The classification of most cases is difficult and must be regarded as tentative until further facts are known It has since been recommended by Rimington (1958)

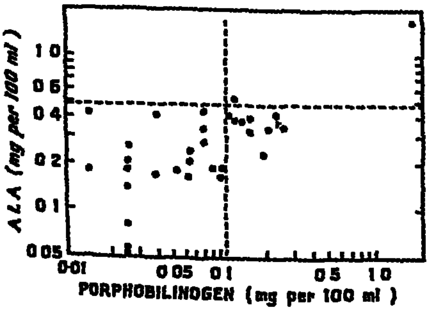

Fig 2—ALA and porphobilinogen urinary excretion of 31 offspring, below 15 years, of patients with latent or manifest porphyria The line parallel to the ordinate corresponds to M+2S D mg porphobilinogen per 100 ml, the line parallel to the abscissa to M+2S D mg ALA per 100 ml (both for children below 15 years) Logarithmic scale

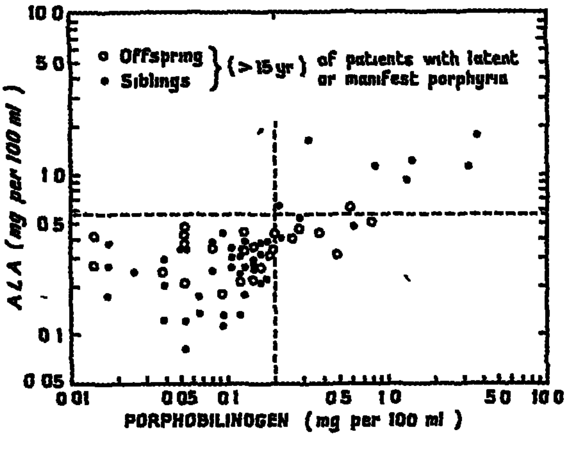

Fig 3—ALA and porphobilinogen urinary excretion of 24 offspring and 45 siblings of patients with latent or manifest porphyria The line parallel to the ordinate corresponds to M+2S D mg porphobilinogen per 100 ml, the line parallel to the abscissa to M+2S D mg ALA per 100 ml Logarithmic scale

Porphyria cutanea tarda symptomatica —This type is mainly characterised by cutaneous symptoms It usually appears in middle age and has a chronic, benign course It is often accompanied by liver dysfunction The excretion of porphobilinogen is usually normal

Protocoproporphyria —This type usually becomes manifest around puberty Here the cutaneous symptoms may be accompanied by colicky pain and rarely by neurological signs During

Bold faced figures exceed M + 2 S.D for the age-group and are therefore considered pathological
* Alcoholic

attacks of colic the porphobilinogen is often increased Large amounts of proto- and copro-porphyrins are present in the fæces even during remissions During attacks the fæces are said to contain less porphyrins and the urine more This reciprocity in the excretory function of liver and kidneys was first noted by Rimington (1952) The large family in South Africa reported by Dean (1953, 1955) certainly represents this type of porphyria

The results of the analyses in cases of porphyria cutanea tarda are shown in table IV

Urine samples from some of the closest relatives of patients 11 and 12 were also analysed A sixteen-year-old son of case 12 showed a slightly increased excretion of δ-aminolævulic acid and porphobilinogen on two occasions without simultaneous increase in the excretion of porphyrins Two older brothers of case 11, on the other hand, showed a normal excretion of δ-aminolævulic acid and porphobilinogen, while the excretion of porphyrins was increased in both The proband (case 11) in this family was a fairly heavy drinker, and it is possible that alcohol, by its toxic effect on the liver, unmasked her latent porphyria It seems quite probable that a genetical defect (a real porphyria) must be present when an alcoholic develops porphyria cutanea tarda

Summary

Quantitative determinations were made of δ-aminolævulic acid and porphobilinogen in the urine from 34 patients with manifest acute intermittent porphyria, from 128 of their closest relatives, and from 12 patients with porphyria cutanea tarda

All patients with latent or manifest acute intermittent porphyria showed a pathologically increased excretion of porphobilinogen in the urine This therefore appears to be an obligatory diagnostic sign In two-thirds of the patients the excretion of δ-aminolævulic acid was also increased

In all apparently healthy but genetically certain carriers of the disease the urinary excretion of porphobilinogen, and usually of δ-aminolævulic acid as well, was increased This suggests that the disease can be transmitted only by persons with latent or manifest porphyria

A third of the apparently healthy children, below 15 years, of patients with latent or manifest acute intermittent porphyria had biochemical disorders suggestive of porphyria It is noteworthy that so many of these children had latent porphyria, since manifest porphyria is very rare in this age-group

In patients with porphyria cutanea tarda the urinary excretion of δ-aminolævulic acid and of porphobilinogen followed no regular pattern Determination of the porphyrin content of the urine and fæces thus appears more useful in the biochemical diagnosis of this type of porphyria

The investigation was supported by grants from the Medical Faculty of the University of Lund

I wish to thank Prof A Querido of Leiden, Holland, and Dr G Dean of Port Elizabeth, South Africa, for contributing urine samples from patients 7, 8, and 9

URINARY infection has long been accepted as the commonest complication of operation on the prostate and bladder, and in fact is often regarded as a necessary evil Infection mostly produces only local inflammation with no serious consequences, and eventually, if all goes well, it dies out some months after the patient has left hospital. Occasionally it may lead to serious and sometimes fatal results by way of secondary hæmorrhage, pyelonephritis, and septicæmia It is therefore obvious that, if these occasional serious consequences are to be avoided, great efforts must be made to maintain sterility of the urine after all urological operations

In the work described here, which has occupied three years, we have had two main objects to investigate the origin and clinical effects of postoperative infection of the urinary tract and blood-stream, and to find means of preventing infection

Methods

Except for some of the patients in whom the clinical effects of infection are described, only those whose urine was sterile before operation are included in this report Of 161 such patients 41 had retropubic prostatectomy and 120 had transurethral operations on the prostate or the bladder They were admitted to four general surgical wards under the care of two surgeons whose technique did not change significantly throughout the investigation Antibiotics and sulphonamides were not given before operation and were only used when the clinical condition of the patient was thought to make them necessary after operation Preoperative drainage was not used, and at operation a plastic or a latex-rubber catheter was placed in the urethra and left in for three days At first open drainage was used A sterile rubber tube connected to the catheter hung over the edge of the bed and drained into a pail on the floor When clots caused obstruction they were either washed out with sterile saline solution or removed by suction from a sterile bladder syringe Later, closed drainage and irrigation were used, as described below

Urine was collected with aseptic precautions by one of us each day, starting on the day before operation and omitting Sundays During the later part of the investigation the following material for culture was taken from patients while in the theatre swabs from the anterior urethra before instrumentation, urine collected when the cystoscope was passed, fragments of prostate removed by resection, and samples of the irrigating fluid After operation, specimens were collected either by disconnecting the catheter from the drainage tube or, when patients were on closed irrigation, with a sterile syringe attached to a needle inserted into the wall of the tube, previously swabbed with tincture of iodine Preliminary tests showed that neither procedure caused contamination of the specimens Urine was examined within two hours of collection by microscopy of wet and gram-stained smears of deposit and by a roughly quantitative cultural technique Six standard loopfuls ($^1/_{150}$ ml) of uncentrifuged urine were placed side by side on well-dried blood-agar and MacConkey plates One loopful was streaked over the remaining surface of each plate, which was then incubated as soon as the other loopfuls had soaked into the medium Colonies were counted and identified after twenty-four hours

The sensitivity of all the bacteria to antibiotics and the biochemical activities of the gram-negative bacilli were determined by standard methods Most strains of *Staphylococcus aureus* were phage-typed (Williams and Rippon 1952)

A patient was considered to have developed an infection only if his urine contained at least 3000 bacteria per ml. on two or more consecutive days This high limit was chosen to eliminate slight or doubtful infections When an organism appeared first in small numbers and later became numerous, the infection was counted as starting on the day of its first appearance. Infections by coagulase-negative staphylococci (*Staph albus*) were not included, because the clinical significance of this organism was often doubtful. It was often found in the urethra and, in small numbers, in otherwise normal urine Though its presence in larger numbers was in some cases accompanied by pyuria, in others there was no evidence of inflammation.

Results

Bacteriology of Urine

Between April 4, 1955, and July 25, 1956, before additional measures were taken to prevent infection. 13 of the 16 retropubic prostatectomies and 29 of the 41 transurethral operations were followed by infection, an overall incidence of 74% The incidence of infection was much higher than was indicated by the clinical signs and symptoms and higher than would have been detected if only one or two random postoperative samples of urine had been examined from each patient, because some infections cleared in a few days The bacteria, in order of frequency, were coliform bacilli proteus, *Staph albus*, *Streptococcus fæcalis*, *Staph aureus*, and *Pseudomonas pyocyanea*, but in many cases the infections were mixed. As we reported previously (Gillespie 1956), many of the bacteria originated in the hospital, as was shown by their abnormal resistance to antibiotics and, in the case of staphylococci, by their phage patterns That cross-infection is often responsible for postoperative urinary infection has been shown by several workers (Ørskov 1952, 1954, Kass 1955, Goldie 1956, Dutton and Ralston 1957) The organisms do not usually come from the patient's own bowel. Gillespie (1956) and Dutton and Ralston (1957) failed to isolate antibiotic-resistant coliform bacilli from the fæces of patients in whom they caused urinary infection.

All the patients with infections had numerous pus cells in their urine, but bacteria often appeared a day or two before the pus Pus cells were rarely numerous in the absence of infection.

Clinical Effects

Pyrexia higher than 100°F on one or more days of the postoperative period was recorded in 48% of 155 patients chosen at random Of the patients who remained without postoperative infection, and whose records showed such pyrexia, 82% were affected in this way only on the first or the second postoperative day Considering, therefore, records of pyrexia from the third day onwards, we found that only 5 of 79 (6%) of patients who remained uninfected showed pyrexia, whereas 42 of 76 (55%) of patients with infection had pyrexia which was probably attributable to the infection

The duration of the infection varied from a few days to more than a year Many patients were followed up, but it was impossible to see all at regular intervals About a third of those who left hospital with an infection had sterile urine after three months, and about two-thirds after six months A few were still infected a year later It seems that infection usually clears up spontaneously when the operation site heals and treatment with sulphonamides or antibiotics is often unnecessary. If used, these drugs usually do not influence the ultimate disappearance of the organisms, whose persistence for a long period often indicates a structural abnormality of the urinary tract.

In a few patients infection had serious consequences, with the development of pyelonephritis In others, not included in this series, we have, during the past two years, seen 1 proved case of subacute bacterial endocarditis and 9 of septicæmia complicating postoperative urinary infection In 5 cases, 2 of which were fatal, the septicæmia was a complication of an established pyelonephritis and caused deterioration in the condition of an already ill patient. In the 4 others, the picture was more dramatic, with sudden collapse of a previously fit patient owing to a profound fall in blood-pressure but combined with a rise of temperature, 1 of these patients died, and the 3 others recovered after prompt energetic treatment with intravenous antibiotics This condition of bacteriæmic shock is an important complication of urological infection and urethral instrumentation (Waisbren 1951, Hall and Gold 1955, Spittel et al 1956 Ezzo and Knight 1957) It may easily be mistaken for massive pulmonary embolism or severe coronary thrombosis if the strange combination of shock and pyrexia is not noticed, and the result is often fatal unless intravenous antibiotics are quickly given Even at necropsy the real cause of death may not be obvious

There is often a rise of temperature, and occasionally a rigor, soon after withdrawal of the indwelling catheter, and it seems likely that the disturbance of an infected operation site may sometimes discharge bacteria into the blood-stream To investigate this possibility, three blood-cultures were made from each of 51 patients of whom 29 had sterile urine and 22 infected urine at the time of operation The first sample of blood for culture was taken immediately before withdrawing the catheter the second within five minutes of its removal, and the third about twenty minutes later

All blood-cultures were negative from 15 patients whose urine remained sterile after operation but of 14 patients who developed postoperative urinary infection 7 had positive blood-cultures from blood taken within five minutes of withdrawing the catheter, whereas their first and third samples of blood were negative. The results with the patients who came to operation with urine already infected suggested that bacteriæmia was less likely with long-standing infection than with recently acquired infection. In 15 of this group whose urinary flora was unchanged after operation no positive blood-cultures resulted from withdrawing the catheters, but of 7 whose urine after operation contained new varieties of bacteria 2 had positive blood-cultures from blood obtained within five minutes of withdrawal (table I) Organisms

TABLE I—BLOOD-CULTURES TAKEN FIVE MINUTES AFTER REMOVING THE INDWELLING CATHETER FROM PATIENTS WITH STERILE AND INFECTED URINE

Urine before operation	Urine when catheter removed	No of patients	Blood-cultures	
			Positive	Negative
Sterile	Sterile	15	0	15
	Infected	14	7	7
Infected	No additional organisms	15	0	15
	Additional organisms acquired	7	2	5
	Total	51	9	42

similar to those causing bacteriæmia were present in the urine of 6 of the patients (Slade 1958)

Evidently, transient bacteriæmia commonly follows the withdrawal of an indwelling catheter from a recently infected urinary tract, and the difference between this bacteriæmia and a septicæmia may be a matter of the number and virulence of the organisms These results recall those of Scott (1929) and Barrington and Wright (1930), who showed that transient bacteriæmia sometimes results from the passage of sounds used to dilate urethral strictures Bacteriæmia was also found by these workers when urine was passed for the first time after dilatation

Sources and Routes of Infection

Culture of prostatic fragments often yielded a few colonies of *Staph albus* but no other organism Bacteria similar to those which caused infection were sometimes isolated from the anterior urethra just before operation but not from numerous swabs of theatre personnel, towels, cystoscopes and other equipment, and sterilising and rinsing solutions On the other hand, it was always easy to find the organisms on ward equipment and furniture Irrigation of the bladder in the ward has been shown to be an important cause of infection, and improvements in drainage and irrigation methods can reduce its incidence (Pyrah et al 1955, Gillespie 1956, Goldie 1956) Dutton and Ralston (1957) showed experimentally that bacteria could ascend to the bladder via the drainage tube and indwelling catheter, and we have found that rising air-bubbles can readily carry organisms up the tube But bacteria must also enter the bladder in other ways, for some patients developed infection even when treated with closed aseptic drainage and no irrigation (Gillespie 1956) We therefore decided to investigate the effects of improving methods of bladder drainage and irrigation and of changing methods of sterilising urethral instruments in the theatre

PREVENTION OF INFECTION

Closed Drainage

The closed-drainage system was set up before the patients left the theatre, by aseptically connecting the indwelling catheter to the sterilised drainage apparatus by means of a 4-ft length of sterile rubber tubing The apparatus was prepared beforehand by inserting a rubber stopper fitted with glass inlet and air filter, previously autoclaved, into a 1 gallon 2-handled clear glass bottle (U G B Co , A L 29), containing 100 ml of liq formaldehyde *B P C* The assembled unit was allowed to stand for at least twenty-four hours before use, because tests showed that cultures of *Escherichia coli*, proteus, *Ps pyocyanea*, and *Staph aureus*, smeared on the inside of the bottle above the level of the fluid, were killed by exposure overnight to the vapour In order to allow the contents to be measured for fluid-balance records, volume scales were printed on paper strips which were fixed to the outsides of the bottles (see figure)

In a controlled trial previously reported (Gillespie 1956) we found that the onset of infection was often delayed, but usually not prevented, by the closed aseptic drainage system Our experience subsequently has been similar As compared with patients on open drainage, many could be brought through the two or three days of catheter drainage after operation without infection, only to develop an infection soon after the catheter was removed

Closed Irrigation

An entirely closed method of irrigation was introduced, so that patients whose catheters became blocked by blood-clot after operation could be irrigated with complete aseptic precautions A 1-litre bottle of sterile saline solution was suspended 1 metre above the bed The air inlet was fitted with a sterile cotton-wool filter kept dry by means of a non-return fitting The delivery tube of the saline bottle was connected to a glass Y-piece by means of a rubber tube fitted with a screw clip The stem of the Y-piece was connected to the indwelling catheter and the other limb to one end of a Higginson syringe from which both valves had been removed The other end of the syringe was connected to the closed drainage bottle (see figure) The bladder was washed out by allowing saline solution to flow up the catheter by gravity If clots prevented this, the saline solution was made to flow into the Higginson syringe until it had displaced all air-bubbles there The supply was then stopped with a screw clip and, pinching the lower tube of the syringe with finger and thumb, the contents of the syringe were forced up the catheter by compressing the bulb with the other hand When suction was needed to move clots from the catheter, the catheter was pinched by finger and thumb and the bulb emptied into the drainage bottle by compression with the other hand The lower tube of the syringe was then pinched just beyond the bulb and the catheter released, thus allowing the bulb to expand and producing enough suction to remove all but very big clots from the bladder These manipulations, although complicated to

Open irrigation	19	5	14	8	1	14

describe, proved easy to demonstrate to the nursing staff, who soon learned to perform them correctly Occasionally, however, this closed method of irrigation failed when bleeding was profuse and clotting pronounced, and the tubing had to be disconnected to allow the use of a sterile bladder syringe With increasing practice these failures have been limited recently to those cases where neither closed nor bladder-syringe irrigation proved successful, and the catheter had to be changed Such difficulties, with their consequent risk of infection, could normally be avoided by careful observation of the patient during the early hours after operation Obstruction to the passage of urine was easy to relieve if dealt with promptly

The effect of using closed irrigation was tested between Aug 1, 1956, and Nov 11, 1957 Some patients, selected at random, had the closed-irrigation apparatus fitted in the theatre The others also had closed drainage but had wash-outs of sterile saline solution from a sterile syringe when clots had to be removed. The result was a disappointingly small improvement Infection developed in 25 (57%) of the 44 patients who either had closed irrigation or required no irrigation, compared with 14 (74%) of the 19 with open irrigation It was seen that the incidence of infection in the immediate postoperative period (up to eighteen hours after operation) was quite unaffected (table II) The reduction in the incidence of infection in the remaining period of catheter drainage was, however, highly significant. On open irrigation, 8 of the 14 patients then "at risk" developed infection before the catheter was removed, whereas with closed or no irrigation, only 3 of 29 patients similarly "at risk" developed infection during drainage (χ^2, corrected for continuity, = 8·5, n = 1, p less than 0·01) Those who had no irrigation of any sort appeared to do best, but the number of patients was too small to be sure of this Patients who required no irrigation may have been less susceptible to infection Patients who survived without infection until the catheter was withdrawn often developed persistent infections within twenty-four hours after the withdrawal The organisms causing these delayed infections did not differ from the others It seemed that bacteria might persist in the operation site, only to be released and sometimes to cause infection after the disturbance of withdrawing the catheter If so, the infections which developed after the removal of the catheter, like the immediate postoperative infections, might be attributable to bacteria introduced in the theatre and would reduce the benefit obtained from aseptic drainage and irrigation of the bladder That this may happen was shown by culturing material adhering to the collapsed bulb of Foley catheters Of 16 catheters removed from patients whose urine was sterile, 4 yielded heavy growths of bacteria other than *Staph albus* Similar organisms were isolated from their urine soon afterwards, but had disappeared by next day and did not cause urinary infection in these particular patients

Changes in Theatre Technique

A study of our records showed that several patients had developed early postoperative infections by organisms similar to those known to be present in the urine of previous patients on the same operating-list (Many patients came to operation with urine already infected following previous instrumentation or operation in this or other hospitals) In 1 instance, the infecting organism was *Staph aureus* phage-type 77, which had not recently been isolated from the patient's own ward where an investigation of staphylococci was in progress, but was present in the urine of an earlier patient on the same list who came from a different ward It seemed clear from these findings, and from the constantly high incidence (about 30%) of early postoperative infection despite improved drainage and irrigation that some infections must originate in the theatre by cross-infection within an operating-list Although swabs taken from time to time from urethral instruments had been sterile, incomplete sterilisation of the instruments was the most likely cause of the cross-infection

Two changes were therefore introduced patients with urinary infections were kept, as far as possible, to the end of the operating-list (an obvious precaution which previously had been overlooked), and the method of disinfecting cystoscopes and resectoscopes was altered Boilable cystoscopes were not available The instruments in use had previously been disinfected between cases by dismantling, rinsing in running water, and immersing for at least fifteen minutes in 1/2000 mercuric oxycyanide solution contained in shallow dishes Hayes (1949) showed that oxycyanide was a poor disinfectant—a fact which we have confirmed Immersion for thirty minutes failed to sterilise strips of metal contaminated with *Staph aureus*, and proteus and coliform bacilli survived for twenty minutes Chlorhexidine ('Hibitane') was found to be a much better disinfectant and sterilised large inocula of the same organisms within ten minutes, using a 1/5000 solution in saline A mixture of hibitane and oxycyanide had a slightly more rapid bactericidal action than hibitane alone Further studies are being made on the bactericidal action of this mixture (Media containing sodium thioglycollate, lecithin, and 'Lubrol' were used for bactericidal tests with the disinfectants) Accordingly, we decided to employ an aqueous solution containing 1/5000 hibitane and 1/2000 mercuric oxycyanide for disinfecting cystoscopes and resectoscopes between operations The instruments were taken apart, washed in running water, and immersed vertically, so

TABLE III—INCIDENCE OF INFECTION WITH "OLD" AND "NEW" ASEPTIC METHODS IN THEATRE (SEE TEXT FOR EXPLANATION)

—	Total patients	Infections				
		Within 18 hr after operation	In remaining catheter-drainage period	In next 24 hr	Subsequently	Total
'Old' method (Aug 1, 1956 to Nov 10, 1957)	44	15	3	4	3	25
'New' method (Nov 11 1957 to March 8, 1958)	30	2	2	3	0	7

All patients had closed or no irrigation and closed drainage.

as to expel air, in tall cylinders containing the disinfectant mixture, for at least twenty minutes These changes were introduced on Nov 11, 1957 Of the 30 patients who had operations after this date only 7 (23%) developed infection, compared with 25 (57%) of the 44 previous patients who also had closed irrigation and drainage (table III) The difference was significant ($\chi^2 = 6\ 8$, n = 1, p less than 0 01) Much of the improvement was due to a striking reduction in the incidence of early postoperative infection

In contrast to the antibiotic-resistant "hospital organisms" which caused many of the infections before Nov 11, those responsible for all 7 subsequent infections were normally sensitive to antibiotics and may have been derived from the patients themselves Urethral swabs showed that organisms similar to those which caused 4 of the infections (a coliform bacillus, a streptococcus, and, on 2 occasions, *Ps pyocyanea*) were present in the anterior urethra before operation, and these may have been carried up by instrumentation

Since the changes in ward and theatre technique were introduced, there has been a gradual reduction in the infection-rate The incidence of postoperative infection has fallen from 74% of the 57 patients treated by the old methods, before August, 1956, to 23% of the 30 patients treated since Nov 11, 1957 The difference is highly significant (χ^2, corrected for continuity = 18 3, n = 1, p less than 0 001) Both types of operation have shared in the improvement, only 2 of the 10 recent retropubic operations and 5 of the 20 recent transurethral operations have been followed by infection

Discussion

Urinary infection is a very common complication of operation on the prostate and bladder, and is usually the result of cross-infection with antibiotic-resistant organisms derived from the hospital and brought about by instrumentation Its true incidence may be unsuspected since it often produces little clinical disturbance Nevertheless it is important to prevent infection, because of its serious results in a minority of patients It sometimes leads to pyelonephritis, which is probably a blood-borne infection resulting from the transient bacteriæmia that we have detected in many of these patients, and this must be particularly dangerous to a patient with impaired renal function Bacteria are most likely to enter the bloodstream during the first few days of an infection while the operation site is still unhealed Their entry may be precipitated by the removal of the indwelling catheter or perhaps by straining at defæcation or micturition The important complications of bacteriæmic shock, septicæmia, and bacterial endocarditis seem likely to be further extensions of this process

The changes in our methods of preserving asepsis during and after operation have considerably reduced our infection-rate and have given us the new and welcome experience of performing urological operations and carrying treatment through to its conclusion in a sterile surgical field The results of culturing preoperative urethral swabs suggest that some infections were caused by bacteria which entered the urethra before operation McLeod (1958) has demonstrated the importance of this mode of infection Another possible route of infection is through the secretion which collects between the urethral wall and the indwelling catheter Although we were previously unable to demonstrate the entry of infecting organisms by this route (Gillespie 1956) the experiments of Kass and Schneiderman (1957) show that it may be important

Summary

Urological patients with initially sterile urine were studied in general surgical wards for a period of three years

Postoperative urinary infection was very common, and was usually caused by antibiotic-resistant bacteria endemic in the hospital Several patients with infected urine suffered transient bacteriæmia when their indwelling catheters were removed It is suggested that such bacteriæmia may sometimes lead to pyelonephritis, septicæmia, bacteriæmic shock, or endocarditis

The infection originated sometimes in the theatre and sometimes in the ward Considerable improvement was achieved by changing the method of disinfecting cystoscopes and resectoscopes and by using of closed aseptic apparatus for draining and irrigating the bladder after operation

We wish to thank the board of governors of the United Bristol Hospitals for a grant towards the cost of this research, and the ward sisters and Mr W Price for their enthusiastic assistance

THE INFLUENCE OF AGE ON EXCRETION OF RADIOACTIVE IODINE

G A MacGregor [*]
M D Lond, M R C P
LATE SENIOR MEDICAL REGISTRAR

H Wagner
M D Johns Hopkins
RESEARCH FELLOW, NATIONAL HEART INSTITUTE, U S A

From the Department of Medicine, Postgraduate Medical School of London, W 12

MEASUREMENT of the urinary excretion of radioactive iodine (^{131}I) has proved valuable in the diagnosis of hyperthyroidism We suspected, however, that this test was not as reliable in the elderly as it was in younger patients To see whether the limits of normality varied with age, a group of euthyroid patients of different ages were reviewed

Material and Methods

In the ^{131}I-excretion test used at this hospital, urine is collected during three periods in the forty-eight hours following the administration of the iodine The percentage of the dose excreted during the 0–8-hour period, the 8–24-hour period, and the 24–48-hour period is measured, and a thyroid-uptake or "T" index is calculated from the formula $T = \frac{(0\text{–}8)\ \text{hours}\ \% \times 100}{(8\text{–}24)\ \text{hours}\ \% \times (0\text{–}48)\ \text{hours}\ \%}$ This procedure gives results relatively independent of renal function The currently accepted normal range of the T-index is 2 8 – 13 (Fraser et al 1953)

---

[*] Now at St Luke's Hospital, Warren Road, Guildford, Surrey

In 1952-57 the test was performed on more than 2000 patients 203 cases (with ages ranging from 20 to 82) were selected from this group To ensure, as far as possible, that these cases were euthyroid, the following criteria were used No patients known to have thyroid or renal disease, or in whom the T-index was greater than 13, were included All cases referred with a provisional diagnosis of hyperthyroidism or myxoedema were likewise excluded, even though the result of the test was within the normal range The reasons for performing the test in the cases chosen for analysis are shown in table I

10 of the 213 tests made on these cases were excluded because errors in urine collection were suspected † The remaining 203 results from 197 patients (147 female and 50 male) were analysed by plotting the T-index, and the excretion values for the individual urine-collection periods against the patient's age

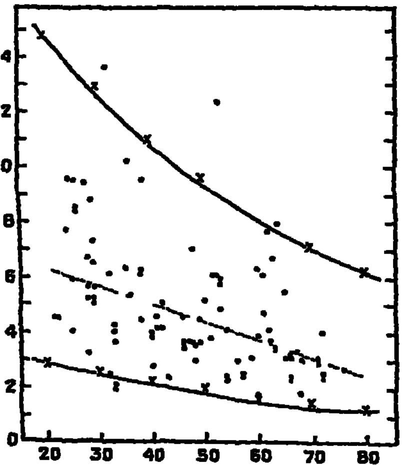

Fig 1—T-index plotted against age The equation for the regression (broken) line is T=7·55 −0·065 age (years) The upper and lower solid lines contain 95% of the points.

Results

In fig 1 it will be seen that the value of the T-index decreases with advancing age This is shown by the calculated regression line, which has a slope of −0·065 T-units per year of age ($P<0·001$) The correlation coefficient of the T-index with age is −0·42±0·07 The distribution of the points suggests that the relationship between the T-index and age may be curvilinear rather than linear A significant decline is also obtained when log T is plotted against age, and the log T-age regression line was used in calculating the limits of normality shown in fig 1 95% of the values lie within these limits

TABLE I—COMPOSITION OF THE GROUP OF PATIENTS WHOSE TESTS WERE COMPARED

Reason for test	Age 20–49		Age 50–82		All ages	
	Tests	Mean T-index	Tests	Mean T-index	Tests	Mean T-index
Before thyroid ablation with ¹³¹I for heart disease	23	4·8	25	4·8		
Before hypophysectomy for cancer	3	4·5	22	3·0		
To exclude hyperthyroidism in clinically euthyroid patients with (a) neurosis	31	5·4	3	4·6		
(b) no apparent disease	38	6·5	38	3·6		
Miscellaneous e g, menstrual disorders	16	4·9	4	4·0		
Total	111	5·6	92	3·8	203	4·8
Selected euthyroid group	47	5·7	19	4·2	66	5·1

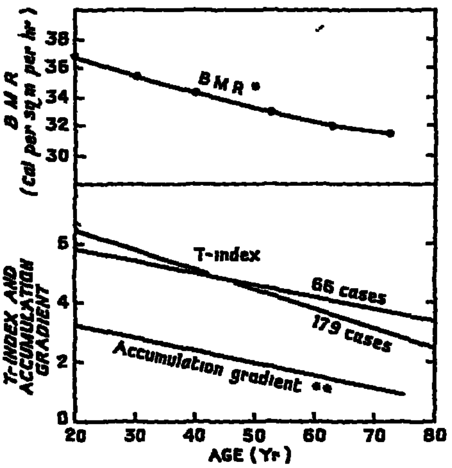

Fig 2—Comparison of the slopes of the regression lines for the T-index and accumulation gradient The fall in the basal metabolic rate is also shown (*from Robertson and Reid 1952, **from Perlmutter and Riggs 1949)

This decline in the T-index might be due to lack of uniformity in the composition of the group Comparison of the diagnoses of the cases above and below 50 years of age shows that there are proportionately more patients with cancer in the older age-group and more cases of neurosis in the younger (table I) However, the decrease is observed even when these cases are discarded Moreover, analysis of the results obtained in an additional group of 66 subjects selected from hospital personnel and outpatients showed a similar decline in the T-index with advancing age In this smaller group, chosen as controls because they were clinically euthyroid, the age range was 20–73 years, the slope of the regression line was −0·042 ($P<0·02$), and the correlation coefficient of the T-index with age was −0·28 ($P<0·02$)

The correlation between age and the percentage of ¹³¹I excreted during the separate collection periods is shown in table II Excretion in the first 8-hour period falls with increasing age The percentage excreted in the 8–24-hour period increases with age, as does that for the entire 48-hour period The fall in the 0–8-hour value could be due to impairment of renal function through ageing The increase in the 8–24-hour and 0–48-hour excretion cannot, however, be explained in this way It is more likely that the increased excretion and the change in the T-index are due to a fall in thyroid uptake

TABLE II—CORRELATION BETWEEN ¹³¹I-EXCRETION AND AGE IN 197 PATIENTS

Urine sample	Correlation coefficient r	Significance P
0–8-hour period	−0·222	<0·01
8–24-hour period	+0·332	<0·001
0–48-hour period	+0·368	<0·001
T-index	−0·420	<0·001

Discussion

A decrease in thyroid uptake with advancing age has been reported in previous ¹³¹I studies Perlmutter and Riggs (1949) found that in a group of 162 euthyroid cases the mean "accumulation gradient", derived from the 1–4-hour neck uptake, fell with each decade from the age of 12 to over 70 Quimby et al (1950), in a survey of 1050 tests on euthyroid patients, also detected a smaller but statistically significant decrease in the 24-hour thyroid uptake with increasing age The rate of decline of the accumulation gradient with age observed by Perlmutter and Riggs (1949) closely resembles that of the T-index in our series Calculated from their data, the slope of the regression line is −0 048 units per year The fall in the thyroid uptake with advancing age in euthyroid patients revealed by these tests also runs parallel to the decrease in the basal metabolic rate (Robertson and Reid 1952) (fig 2) An age-correction factor, such as is used for the basal metabolic rate, would therefore probably increase the sensitivity of the ^{131}I-excretion test Our data suggest that in patients over 50, results in the " upper normal " range (T-index 9–13) may indicate hyperthyroidism

---

† In every test the T-index was compared with the 0–48-hour excretion value The results were outside the range found in 95% of cases, in the 10 rejected tests

Summary

^{131}I-excretion tests in a series of euthyroid patients were analysed The results showed that the uptake of ^{131}I by the thyroid gland decreases with advancing age

We gratefully acknowledge advice and assistance from Prof Russell Fraser, and assistance in the statistical analysis from Mr N W Please

THE EFFECT OF INSULIN-BINDING ANTIBODIES ON INSULIN SENSITIVITY

N Kalant
M D Toronto

C Gomberg
M D McGill

R Schucher
Ph D McGill

From the Department of Investigative Medicine, McGill University, and Research Laboratory, Jewish General Hospital, Montreal

By the use of ^{131}I-labelled insulin, two abnormalities of insulin metabolism have been demonstrated in the sera of patients previously treated with insulin (*a*) binding to serum-globulins (Berson et al 1956), and (*b*) delayed disappearance from the circulation (Berson et al 1956, Welsh et al 1956) It has been suggested that repeated administration of insulin results in the formation of specific antibodies which migrate electrophoretically as globulins, injected insulin then becomes attached to the circulating antibody and is retained in the plasma instead of undergoing its normal course of degradation (presumably by tissue insulinase (Berson et al 1956) Furthermore, since insulin must be in contact with cells to exert its biological action, it has been postulated that binding to antibody would prevent such contact and result in apparent insulin unresponsiveness (Welsh et al 1956)

Various studies have clearly shown that patients with gross insulin resistance do have serum-globulin components which are probably antibodies, and which have an insulin-neutralising effect when injected with insulin into mice (De Fillipis and Iannocone 1952, Sehon et al 1955, Colwell and Weiger 1956) But it is still uncertain whether the " ordinary " diabetic patient acquires a significant degree of resistance to insulin as the result of antibodies developing

We have attempted to test the hypothesis concerning the effects of insulin antibodies and to determine the clinical significance of such antibodies

Methods

The patients studied had maturity-onset diabetes (recognised after age 35), but no other recognisable metabolic disturbance Fourteen had been treated with insulin for 6 months or longer, while eleven had not received insulin therapeutically

Insulin responsiveness in the patients was determined by a procedure based on measurement of blood-glucose half-life (Heller, Kalant, and Hoffman) A glucose load was administered intravenously over 5 minutes, and 20 minutes was allowed for its equilibration in body fluids During this interval a glucose infusion was given at a rate sufficient to maintain a raised blood-sugar concentration Over the next 30 minutes samples of capillary blood were obtained every 5 minutes, and from these the rate of fall of blood-sugar and its half-life ($t_{\frac{1}{2}}$G) were calculated Insulin[1] (0 1 u per kg) was then injected intravenously and sampling was continued for the next 30 minutes to permit calculation of blood-sugar half-life after insulin ($t_{\frac{1}{2}}$I)

In rabbits insulin responsiveness was assessed after the intravenous injection of crystalline insulin, 0 2 u per kg , by measuring the blood-glucose concentration every 10 minutes for 90 minutes and determining, in arbitrary units, the area between the time-curve of glucose concentration and the base-line drawn at the level of the initial concentration The dose of insulin was found by preliminary experiment not to produce a maximum hypoglycæmic effect in normal rabbits

Paper electrophoresis of serum containing labelled insulin was performed using 50 µl of serum applied in a line 3 inches toward the cathode from the middle of the strip, and allowed to move to the middle by hydrodynamic flow (Berson et al 1956) before electrophoretic separation The strips were dried and stained, and divided into eight sections albumin, α_1, α , β, and γ globulins, a band extending 1 cm on either side of the line of application (origin), the band between γ-globulin and origin, and a blank taken from the area on the anodal side of the albumin Eight strips were run simultaneously for each sample of serum and the appropriate segments pooled for assay of radioactivity in a scintillation well counter

Boundary electrophoresis was carried out in a Perkin-Elmer apparatus, model 38A, with barbitone buffer, pH 8 6, ionic strength 0 1 Aliquots of the serum were removed after resolution, by means of a needle-tipped pipette, by observation of the Schlieren pattern on the ground-glass screen it was possible to remove, from the descending limb, aliquots containing γ, $\gamma+\beta$, and $\gamma+\beta+\alpha_2$ globulin, and from the ascending limb those of albumin $+\alpha_1$ globulin, and of albumin $+\alpha_1+\alpha$ globulin Each aliquot was measured for total protein, by biuret reaction or nitrogen determination, and for radioactivity A concentration diagram of serum components was drawn from the Schlieren pattern and the relative composition of each aliquot removed from the electrophoresis cell was calculated (fig 1)

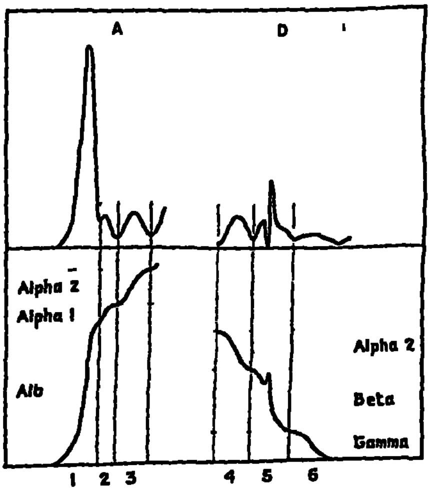

Fig 1—Method of calculating specific activities of serum-proteins after separation by moving-boundary electrophoresis

Above Schlieren pattern Below Concentration diagram of serum components calculated from the Schlieren pattern Specific activities of albumin and , -globulin were calculated directly, their contribution of radioactivity to segments 2 and 5 were calculated, and specific activities of α_1 and β then obtained by difference A ascending limb D descending limb

---

[1] Insulin labelled with ^{131}I was obtained commercially, it had a specific activity varying from 3 to 6 mc per mg

By reference to the total protein measurements it was then possible to calculate the actual composition of each aliquot

The specific activities were measured directly for the first aliquot removed from each limb (γ-globulin from the descending and albumin-α_1 from the ascending) From the composition of the second aliquots ($\gamma+\beta$ from the descending, albumin $+\alpha_1+\alpha_2$ from the ascending) the contribution of γ and albumin-α_1 to the radioactivity of these fractions was calculated, and by difference the specific activity of β and α_2 were obtained In some cases albumin was obtained separately from α_1-globulin, the specific activity of the latter was then calculated from the second ascending aliquot, and that of α_2 was taken as the mean value obtained from the third aliquots of each limb

To study the rate of removal of insulin from plasma, a known amount of insulin-^{131}I was injected intravenously, the serum radioactivity precipitable by 10% trichloroacetic acid was measured 15 minutes later and expressed as percentage of injected dose present in the circulating plasma volume (as calculated from surface area and hematocrit) (Welsh et al 1956) In the experiments on patients this procedure was used simultaneously with measurement of insulin responsiveness, the total dose of injected insulin (labelled + carrier) being that necessary for the latter purpose In the rabbit experiments the two parameters were measured on different days The choice of the 15-minute interval minimised the relative importance of radiation-damaged insulin, which apparently has a longer half-life in serum than does native insulin (Berson et al 1956)

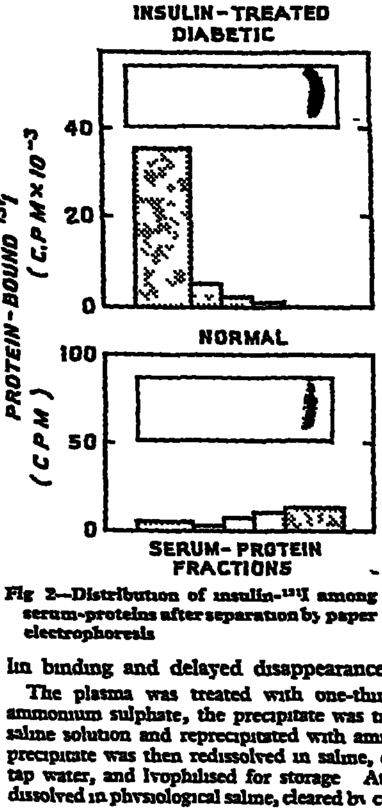

Fig 2—Distribution of insulin-^{131}I among serum-proteins after separation by paper electrophoresis

Rabbits were actively immunised against beef insulin[2] by the method of Arquilla and Stavitsky (1956) Passive immunisation was performed with plasma-proteins obtained from diabetic patients who demonstrated the phenomena of globulin binding and delayed disappearance of ^{131}I-insulin.

The plasma was treated with one-third volume of saturated ammonium sulphate, the precipitate was taken up in physiological saline solution and reprecipitated with ammonium sulphate The precipitate was then redissolved in saline, dialysed against running tap water, and lyophilised for storage At the time of use it was dissolved in physiological saline, cleared by centrifugation and infused into the femoral vein The amount of protein in the infusions varied from 0·5 to 1·0 g in 85–100 ml

Insulin-neutralising activity of serum was assessed in groups of five mice previously fasted for 6 hours

The glucose concentration of tail blood was measured before and 45 minutes after the intraperitoneal injection of insulin (2 or 6 milliunits in 0·01 ml) mixed with 0·2 ml of serum, the fall in glucose concentration was compared with that produced by the same amounts of insulin injected with 0·2 ml saline Blood-sugar was measured by Somogyi's (1952) modification of the Nelson method

Results

Insulin Responsiveness in Diabetic Patients

In agreement with the results of Berson et al (1956) it was found that the insulin-treated diabetic patients retained labelled insulin in their circulation longer than the untreated diabetic patients, and on paper electrophoresis most of it was found to be associated with γ-globulin On electrophoresis of serum from untreated patients most of the radioactivity remained at the origin, and the remainder showed no preferential association with a particular protein component (fig 2)

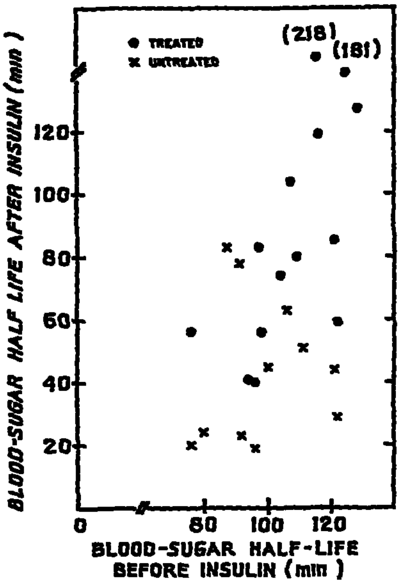

Fig 3—Relation between half-life of blood-sugar before insulin and that after insulin (0·1 u per kg) in treated and untreated diabetic patients

It has been previously shown for diabetics that, as the half-life of blood-glucose without insulin ($t_{\frac{1}{2}}G$) increases, there is a concomitant increase in the half-life after an injection of insulin ($t_{\frac{1}{2}}I$) (Heller, Kalant, and Hoffman) Consequently, to facilitate comparison of the insulin response of two groups, subjects having the same range of values of $t_{\frac{1}{2}}G$ were chosen When they were thus selected, the untreated diabetic patients were found to have lower values for $t_{\frac{1}{2}}I$ (44±7 minutes) than the treated diabetic patients (94±14 minutes), indicating a greater fall in $t_{\frac{1}{2}}$ in response to insulin ($P<0·01$) in untreated diabetics (fig 3 and table I)

The response to insulin may be defined as ($t_{\frac{1}{2}}G-t_{\frac{1}{2}}I$), since in non-diabetic subjects $t_{\frac{1}{2}}I=20±6$ minutes

A = not treated with insulin.
B = treated with insulin.

---

[2] Zinc insulin crystals were kindly supplied by Dr W R Kirtley of Eli Lilly and Co Indianapolis Ind and by Dr R G Romans, Connaught Laboratories, University of Toronto

(Heller, Kalant, and Hoffman), the normal insulin response may be taken as (t_1G–20) The relative response in diabetic patients can then be calculated as the ratio $\frac{t_1G - t_1I}{t_1G - 20}$ There was no significant degree of correlation between the insulin response so calculated, on the one hand, and the serum retention of insulin or binding of insulin to serum-globulin on the other (table II) There was a positive correlation between the latter two parameters

Active Immunisation of Rabbits to Insulin

Six normal adult rabbits were immunised against crystalline beef insulin Before and after this process, four parameters of insulin metabolism were studied (1) insulin responsiveness, (2) the globulin-binding of insulin-^{131}I, (3) the rate of disappearance from the circulation of injected insulin-^{131}I, and (4) the presence of circulating insulin-neutralising activity In addition, the sera of the immunised rabbits was tested [3] for insulin antibodies by the method of Arquilla and Stavitsky (1956) The results (table III) indicate that immunisation led to the development of hæmagglutinating antibodies to insulin, a decrease in the rate of disappearance of insulin from the circulation, and globulin-binding There was a direct relation between the amount of insulin remaining in the plasma 15 minutes after administration and the proportion of this which was "bound" to serum-globulin (fig 4) After immunisation five of the six animals showed an increase in insulin responsiveness, but the mean change was not significant at the 5% level None seemed to have developed a measurable titre of insulin-neutralising activity (table IV)

Passive Immunisation of Rabbits to Insulin

Globulin-binding and the disappearance rate of insulin were studied in five rabbits 36–40 hours after passive immunisation with insulin-binding serum obtained from diabetic patients Such treatment resulted in a variable increase in globulin-binding of ^{131}I-insulin but did significantly slow the removal of insulin from the circulation (fig 3)

TABLE IV—ASSAY FOR INSULIN-NEUTRALISING ACTIVITY IN RABBIT SERUM BEFORE AND AFTER IMMUNISATION WITH INSULIN

Animal	Insulin dose (milliunits)			
	2		6	
	Before	After	Before	After
1	36	38	50	53
2	16	23	25	46
3	25	12	53	29

5	22	42	41	76
6		21		39

Values represent the mean fall in blood-sugar (mg per 100 ml) in five mice 45 minutes after injection of serum-insulin mixture The fall in blood sugar produced by insulin alone was
2 milliunits, 13 ± 10 mg
6 milliunits, 30 ± 15 mg

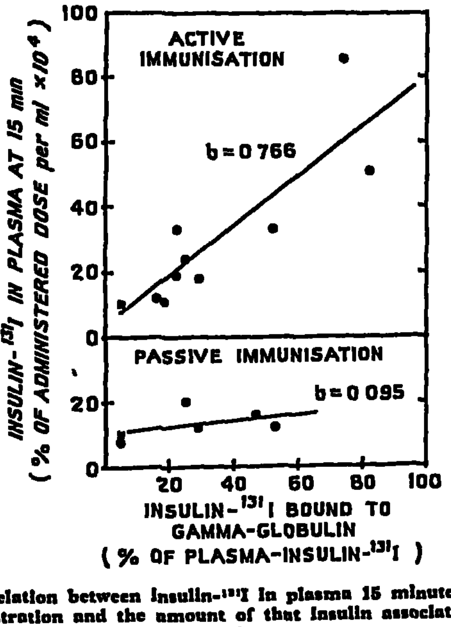

Fig 4—Relation between insulin-^{131}I in plasma 15 minutes after administration and the amount of that insulin associated with γ-globulin on paper electrophoresis

Upper results of 9 tests in six rabbits actively immunised by repeated injection of insulin Lower Results in five rabbits passively immunised by infusion of serum-proteins from insulin-treated diabetic patients Symbol (▪) in lower left corner represents mean normal values

Location of Insulin-binding Globulin

Characteristic examples of the results obtained on fractionation of serum-insulin-^{131}I mixtures by moving-boundary electrophoresis are shown in table V When serum from a non-diabetic subject was used, the insulin moved principally with the albumin and α_1-globulin With serum from an insulin-treated diabetic patient, the insulin was associated principally with the β-globulin, although on paper electrophoresis it apparently moved with γ-globulins Addition of excess insulin to diabetic serum resulted in movement of radioactivity with all protein fractions, when the serum-insulin mixture was passed through a powdered cellulose column (15 × 0 8 cm) most of the radioactivity remained on the column, and that which passed through the column with the serum showed the expected association with β-globulin on subsequent free electrophoresis These results confirm by boundary

TABLE V—DISTRIBUTION OF INSULIN-^{131}I IN SERUM AFTER ELECTROPHORESIS

—	Albumin	α_1	α_2	β	γ
Normal serum	58	17	5	16	3
Diabetic serum	3	4	3	83	7
Diabetic serum + excess insulin	17	27	31	20	2
Diabetic serum + excess insulin passed through cellulose column		17	8	65	9

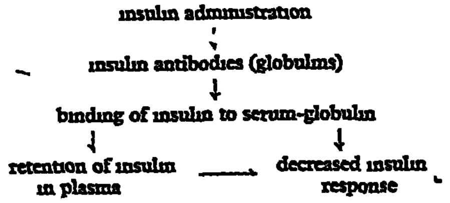
Values represent percentage of total serum activity electrophoresis the results obtained with paper electrophoresis (Berson et al 1956) and alcohol fractionation (Berson and Yalow 1957)

---

[3] Dr E R Arquilla and Dr A B Stavitsky kindly carried out these tests

Discussion

The hypothesis under examination may be expressed diagrammatically thus



insulin administration
insulin antibodies (globulins)
binding of insulin to serum-globulin
retention of insulin in plasma
decreased insulin response

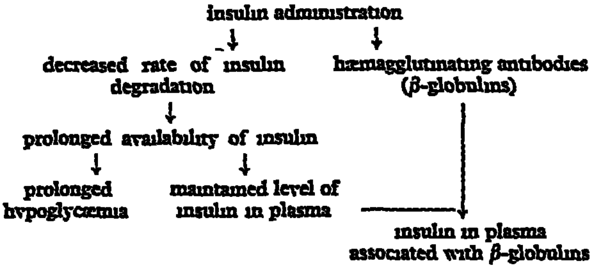
Diabetic patients previously treated with insulin had less response to insulin than diabetics who had comparable impairment of carbohydrate tolerance (t½G the same in both groups) but had not been treated with insulin This finding is compatible with the above hypothesis However, contrary to what might have been expected, there was no apparent correlation between insulin response and degree of binding of insulin to serum-globulin Furthermore, the untreated subjects were for the most part newly discovered diabetics, and possibly they would have shown a further impairment of insulin response with time alone In addition, since diabetes is not a disease entity of single ætiology, there are undoubtedly several unknown and uncontrolled factors affecting insulin responsiveness in groups of patients such as these

The likelihood of such variation was less in the rabbit experiments, in which normal animals were used Here it is evident that administration of insulin led to the development of hæmagglutinating antibodies, to globulin-binding of insulin, and to delayed disappearance of insulin from the circulation Except for one animal, however, there was no evidence of diminution of response to insulin, and indeed there may have been an increased response Moreover, after immunisation there was no evidence of circulating insulin-neutralising activity It therefore appears that neither retention of insulin in the plasma, binding to serum-globulin, nor the presence of hæmagglutinating antibodies to insulin inhibits the action of insulin

The low incidence of insulin resistance in these animals is comparable to that obtained by Lowell and Franklin (1949) with similar methods in a larger group of animals Moloney and Coval (1955) were also unable to produce insulin-neutralising antibodies in the rabbit.

The infusion into rabbits of serum-proteins from treated diabetic patients resulted in "passive transfer" of globulin-binding of insulin, but not of retention of insulin in the circulation Hence we may conclude that binding of insulin by globulin is not the cause of insulin retention

The results described are not compatible with the hypothesis as stated above, but are compatible with an alternative hypothesis This is that long-continued administration of insulin results in two abnormalities (*a*) a primary decrease in the rate of insulin degradation, leading to passive retention of insulin in the circulation and to a prolonged insulin effect, and (*b*) the appearance of circulating antibodies which form with insulin a loose complex which does not inhibit either degradation or the association of insulin with tissues, and consequently does not inhibit the response to insulin or affect the rate of its removal from the circulation The latter phenomenon does not conform to the generally accepted idea that antibody increases the rate of removal of antigen from the circulation, and suggests that the insulin-binding globulin may not in fact function as an antibody in the usual sense These relationships may be presented schematically



insulin administration
decreased rate of insulin degradation
hæmagglutinating antibodies (β-globulins)
prolonged availability of insulin
prolonged hypoglycæmia
maintained level of insulin in plasma
insulin in plasma associated with β-globulins

The decrease in the rate of degradation may be due to a humoral factor, since plasma from patients showing insulin retention can apparently inhibit insulin degradation in vitro (Welsh et al 1956)

Such a hypothesis is not incompatible with certain diabetics having insulin resistance, of varying degree, related to the formation of antibodies, but such antibodies appear to differ from those which are only the result of repeated administration of insulin

The electrophoretic analyses confirm the finding of Berson and Yalow (1957) that the "insulin-binding protein" is a β-globulin rather than a γ-globulin When the binding capacity of this protein was reached, excess insulin travelled with other proteins in a non-specific manner, exposure to cellulose removed the "excess" insulin, so that the remainder had the expected distribution pattern It must be emphasised that the actual specific activity values obtained for γ-globulin and albumin may be considered accurate, but the remainder, being obtained by difference, are only approximations

Conclusions

1 Diabetic patients previously treated with insulin had less insulin response than diabetic patients who had not been previously treated The insulin response was apparently not related to the degree of globulin-binding of insulin or to the degree of insulin retention in the circulation

2 Repeated injection of insulin into normal rabbits led to the development of hæmagglutinating antibodies to insulin, the removal of insulin from the circulation was altered, and binding of insulin to serum-globulin was demonstrable There was no evidence of a decrease in the hypoglycæmic response to insulin or of the presence of anti-insulin activity in the serum

3 Infusion, into normal rabbits, of serum obtained from insulin-treated diabetics led to the globulin-binding of insulin but did not alter the rate of insulin removal

4 It is concluded that insulin-binding antibodies and hæmagglutinating antibodies are not responsible for decreased responsiveness to insulin or for its slower removal from the circulation

5 Moving boundary electrophoresis indicates that the insulin-binding antibodies are β-globulins

MONILIAL PERITONITIS AS A COMPLICATION OF PREOPERATIVE INTESTINAL STERILISATION

MOGENS ANDREASSEN
M D Copenhagen
OF RIGSHOSPITALET, COPENHAGEN

KNUD RIEWERTS ERIKSEN
M D Copenhagen
OF THE INSTITUTE FOR GENERAL PATHOLOGY, UNIVERSITY OF COPENHAGEN

AKSEL STENDERUP
M D Aarhus
OF THE INSTITUTE FOR GENERAL PATHOLOGY, UNIVERSITY OF AARHUS

MONILIAL peritonitis seems to be very rare We have only been able to find one published case (Reynell et al 1953) The patient was a man, aged 49, who was treated with corticotrophin and aureomycin for suspected periarteritis nodosa and had a duodenal ulcer After three days' treatment peritonitis developed, and the patient died four days later Necropsy revealed a perforated duodenal ulcer and peritonitis, *Candida albicans* was cultured from the peritoneal cavity It was assumed that the chemotherapy had changed the intestinal flora in favour of *C albicans*, which entered the peritoneal cavity through the perforated ulcer and caused the infection

We have observed a similar case, which is described below

Case-report

A girl, aged 4 years, had had sluggish bowel movements since birth For six months before admission her constipation increased in severity, becoming associated with abdominal distension, attacks of pain, and vomiting Radiography having revealed megacolon, an operation was advised From the day before operation phthalylsulphathiazole 3 g six times daily for two days and duostreptomycin 1 ml thrice daily for seven days were given orally together with procaine penicillin 200,000 units daily

Operation revealed segmental dilatation, mainly of the transverse colon, the lower portion of the descending colon, the sigmoid, and the rectum being normal The colon was resected from 8 cm above the ileocæcal valve to the lower portion of the descending colon, with end-to-end anastomosis

Postoperative course—The immediate postoperative course was uneventful, but on the eighth day pyrexia developed, for which reason the dosage of penicillin was increased to 1,000,000 units twice daily On the eleventh postoperative day increasing pneumoperitoneum, with distended abdomen but without peritoneal reactions, was noted It was supposed to be due to a small leakage at the site of the anastomosis, but, owing to the surprisingly good general condition of the patient and the absence of signs of peritonitis, further developments were awaited During the next few days the patient began to whimper, the abdominal distension increased, and incipient paralytic ileus developed, but signs of peritonitis were still absent (temperature 38 2 C)

Reoperation on the sixteenth postoperative day revealed a peculiar diffuse inflammation with dense adhesions of the intestines The picture did not resemble that of purulent peritonitis, pus was absent, but the intestines were covered by dry fibrinous flakes The anastomosis was found to be leaking slightly, so the anastomosis was transformed into a colostomy Culture of material from the peritoneal cavity yielded a heavy growth of *C albicans* but no bacteria

Postoperatively gastric paralysis developed, but intestinal function was resumed on the fourth postoperative day Pus discharged from the colostomy for some time, cultures of it produced *C albicans*, proteus, and enterococci Chemotherapy with various drugs led to gradual improvement, and the patient was discharged cured four months after the first operation

Discussion

It can scarcely be doubted that the chemotherapy given immediately before and after the first operation had changed the intestinal flora, with the result that it mainly consisted of *C albicans*, which entered the peritoneal cavity through the leaking anastomosis and caused the peritonitis

It is well known that various combinations of chemotherapeutic agents and antibiotics used for so-called intestinal sterilisation before major abdominal operations only remove the intestinal bacteria, the fungi normal to the intestines continuing to proliferate until they ultimately constitute the greater part of the intestinal flora Although fungi are usually considered to be of low virulence, they may, as in the present case, give rise to severe infection It must be assumed that the peritoneum was not contaminated during the operation, but that the intestinal leakage persisted for some time, during which large amounts of *C albicans* entered the peritoneal cavity

The chemotherapy used has no effect on the fungi It may therefore seem strange that the patient, who had severe peritonitis, recovered However, the human body usually has a strong resistance to *C albicans*, and the peritonitis presumably developed only because fungi had constantly entered the peritoneal cavity before the colostomy was established

Cases of this type are undoubtedly rare, but the case reported here shows that preoperative intestinal sterilisation is not without hazards

Summary

A case of monilial peritonitis in a girl, aged 4 years, whose colon had been resected for megacolon, is reported It is assumed that preoperative chemotherapy to sterilise the intestine changed the intestinal flora, with the result that it mainly consisted of *C albicans*, which penetrated into the peritoneal cavity through a leaking intestine

EFFECT OF A LAMINARIN SULPHATE (LM 46) ON BONE GROWTH

S S ADAMS
Ph D Leeds

HAZEL M THORPE
B Sc Lond

OF THE BIOLOGY DIVISION, RESEARCH DEPARTMENT, BOOTS PURE DRUG CO, LTD, NOTTINGHAM

L E GLYNN
M D Lond, M R C P
DIRECTOR OF PATHOLOGY, RHEUMATIC RESEARCH UNIT (M R C.), CANADIAN RED CROSS MEMORIAL HOSPITAL, TAPLOW, BUCKS

LAMINARIN is a polysaccharide consisting of approximately 20–30 glucose units joined by β–1 3 linkages, and occasionally a β–1 6 linkage (Connell et al 1950, Percival and Ross 1951, Friedlaender et al 1954) It is obtained from certain brown seaweeds and occurs in two forms—" soluble laminarin " from *Laminaria digitata*, and " insoluble laminarin " from *L cloustoni* The latter can be sulphated to produce soluble compounds with varying numbers of sulphate groups per glucose unit Several of these products have been examined previously for anticoagulant activity and toxicity, both of which increase with sulphation (Adams and Thorpe 1957)

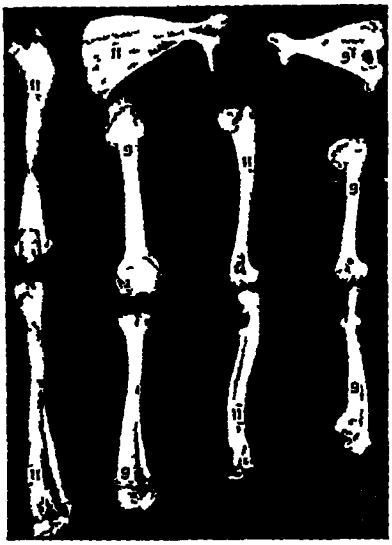

Fig 1—Bones (a) from rabbit (9) treated with LM 46 30 mg per kg intravenously daily for 24 days, (b) from control rabbit (11) which received heparin 10 mg per kg intravenously daily for 23 days

Note small size of bones from rabbit treated with LM 46 and considerable deformity of bone ends, especially at knee and shoulder

We have studied in more detail other laminarin sulphates prepared from laminarin derived from *L cloustoni*, one of which—LM 46—was more toxic and more highly sulphated than the others Initial experiments revealed that this compound had an anticoagulant activity equivalent to 33 heparin units per mg when tested by the sulphated whole blood method (Adams and Smith 1950) The acute intravenous L D 50 to mice was approximately 1500 mg per kg, but the "anaphylactoid" reaction (Walton and Ricketts 1954) was produced in guineapigs by intravenous doses of 100 mg per kg body-weight These results are similar to those reported for laminarin sulphate K (Adams and Thorpe 1957) However, on protracted dosing to rabbits, guineapigs, and rats, LM 46 produced effects which were quite different from those reported for other laminarin sulphates, and which we believe have not been recorded previously for sulphated polysaccharides We give here a preliminary report of these findings, particularly of the skeletal changes

Methods

LM 46 was administered subcutaneously or intravenously to rabbits, guineapigs, and rats on 5 days of each week for 2–9 weeks Rabbits received 15, 30, and 60 mg per kg body-weight, rats 15 and 30 mg per kg, and guineapigs 15 mg per kg daily The ages of the animals at the start of the experiments were rabbits 6–8 weeks, rats 3–4 weeks, and guineapigs 6–8 weeks Control animals, littermates in the case of the rabbits, received a dose of heparin equivalent in anticoagulant activity to the laminarin sulphate

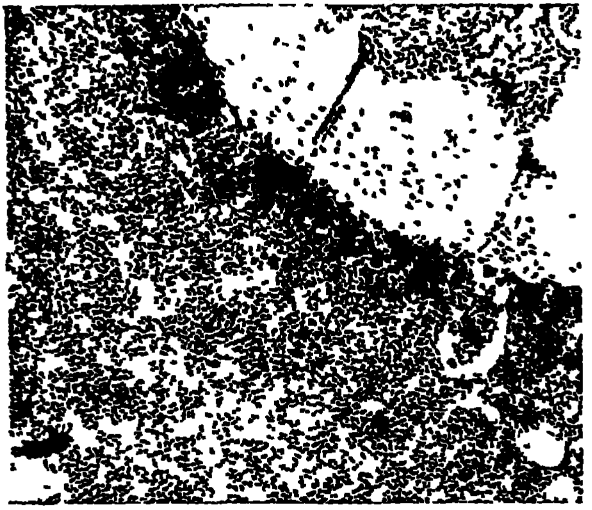

Fig 2—Epiphyseal plate at lower end of femur of rat treated for 49 days with laminarin sulphate LM 46 at 15 mg per kg subcutaneously daily (Hæmatoxylin and eosin ×75)

There has been complete arrest of maturation of cartilage with consequent failure of endochondral bone formation in metaphysis

When the animals became moribund they and the heparin controls were killed with intravenous barbiturate, and soft tissues and long bones were taken for histological examination The remainder of the skeleton was retained for preparation of dry bone specimens

Results

In all animals there was a pronounced loss of weight after prolonged dosing, and they seemed very frail both in appearance and when handled The rabbits and guineapigs had a white discharge in the eyes

The most interesting effects, however, were the skeletal abnormalities, which were most striking in the rabbits,

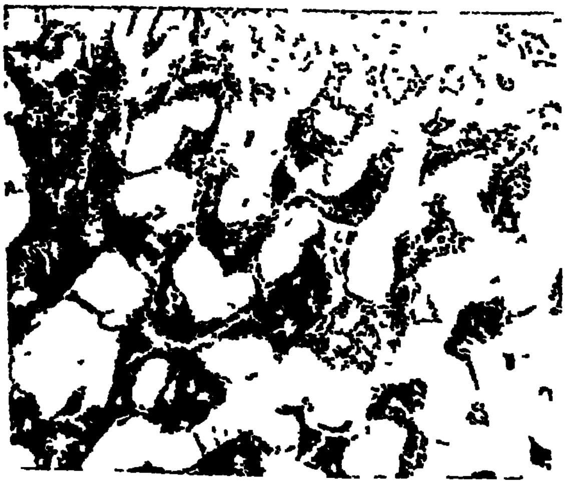

Fig 3—Epiphyseal plate at lower end of femur of control rat treated with heparin at 10 mg per kg subcutaneously daily for 49 days (Hæmatoxylin and eosin ×75)

Endochondral ossification is proceeding normally, resulting in rich network of newly formed bone trabeculæ in metaphysis

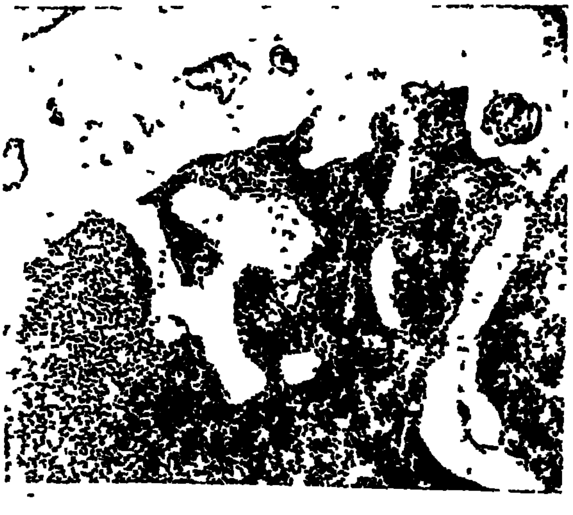

Fig 4—Lower epiphysis of same femur as in fig 2. Bone trabeculae normally present have been almost completely removed (Hæmatoxylin and eosin ×75)

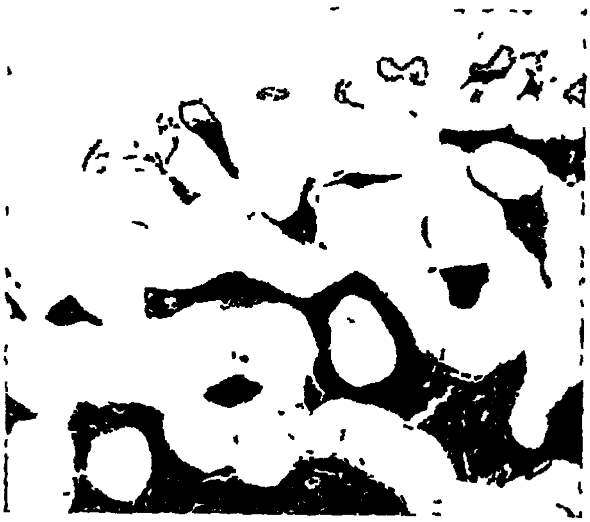

Fig 5—Lower epiphysis of the same femur as in fig 3 Rich network of bone trabeculae is in striking contrast to that in fig 4 (Hæmatoxylin and eosin ×75)

sometimes after only a few days of dosing Initially, the carpal joints became knobbly, and later the condition worsened until these joints were grossly abnormal and caused pronounced splaying of the feet either inwards or outwards Later there was weakness in the pelvic region which sometimes developed into complete paralysis In some animals the femur fractured

In rats the 15 mg per kg dose produced its effects more slowly than in the rabbit, and the forelimb distortion was less obvious, but there was definite weakness in the pelvic region, and distinct kyphosis developed In guineapigs the effects were similar to those in the rabbit, but they appeared more gradually

Both macroscopically (fig 1), and histologically the changes were greatest at the growing ends of the long bones In guineapigs and rats normal maturation of the cartilage cells in the epiphyseal plate was lacking, and there was deficient invasion of this zone by capillaries from the adjacent marrow There was, in consequence, almost complete absence of new bone trabeculæ in the metaphysis (figs 2 and 3) There was simultaneous loss of bone trabeculæ in the epiphysis (figs 4 and 5), which, in extreme cases, was reduced to a shell of cortical bone enclosing the vascular marrow The epiphysis then collapsed (fig 6), and this resulted in pronounced deformity of the articular surface with hæmorrhage and necrosis of the epiphyseal marrow Similar but less severe hæmorrhages and necrosis were sometimes seen in the metaphysis In rabbits the maturation of the cartilage cell columns appeared normal, but very little bone was deposited on the cartilaginous trabeculæ despite striking hyperplasia of osteoblasts in the metaphysis Necrosis commonly overtook these defective bone trabeculæ

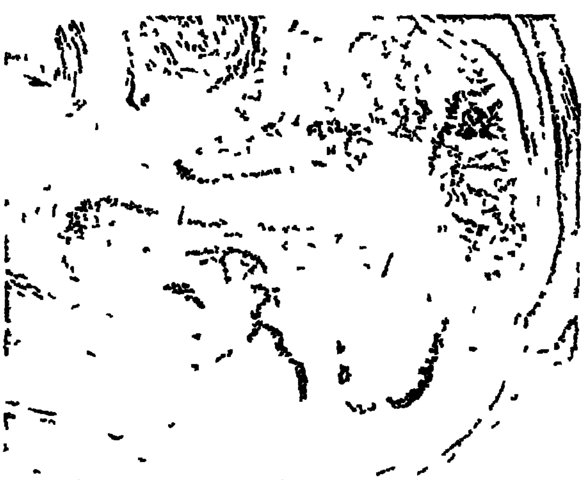

Fig 6—Shoulder-joint of rabbit treated for 24 days with laminarin sulphate LM 46 at 30 mg per kg intravenously daily (Hæmatoxylin and eosin ×3 approx)

Head of humerus has collapsed owing to absorption of bone trabeculæ in head, and defective endochrondal bone formation in metaphysis Epiphyseal plate is itself disrupted into several fragments

In addition to the bone lesions all the animals showed accumulation of metachromatic material in the reticulo-endothelial system and in the proximal convoluted tubules of the kidneys

Discussion

The bone lesions that develop after repeated injections of this particular laminarin sulphate appear to depend primarily on disturbance of the endochondral bone formation that normally takes place on the diaphyseal side of the epiphyseal cartilage In rats and guineapigs the normal sequence of maturation of the cartilage cells is impaired, and this is associated with virtually complete absence of the vascular invasion that normally precedes the actual deposition of bone on the newly formed tongues of calcified cartilage In rabbits it is apparently this deposition of bone which is impaired It is not at present possible to say how these disturbances are brought about by the laminarin sulphate, but its structural similarity to chondroitin sulphate suggests that it might be acting by interfering with the normal metabolism of chondroitin sulphate, especially at sites where the turnover-rate of the normal polysaccharide is high There is, moreover, some evidence that the effect of this laminarin sulphate may be shared by other sulphated polysaccharides Thus, L L Coleman (cited by Regelson and Holland 1958) found osteoporosis in rabbits receiving injections of either polyethylene sulphonate or heparin, and fractures in cholesterol-fed rabbits receiving repeated injections of heparin have been reported by Gillman and Naidoo (1957) A study of the mechanism by which these sulphated polysaccharides produce bone lesions should provide valuable information about the normal processes of endochrondral bone formation

Addendum

Since this paper was prepared H C Hint and A W Richter (*Brit J Pharmacol* 1958, **13**, 109) have reported similar findings in the rabbit following the chronic administration of dextran sulphate They do not, however, refer to forelimb deformities such as we have reported here, and which we have also found following the administration of clinical-size dextran sulphate We have noted that forelimb deformities occur only in very young rabbits, and for that reason used animals aged 6–8 weeks Hint and Richter used animals 5–6 months old—an age at which we would not expect the forelimb deformities to be obvious, except perhaps at necropsy

Preliminary Communication

A SINGLE-PUMP BUBBLE OXYGENATOR

THE deliberate foaming of blood as a means of oxygenation was described by Schroeder[1] in 1882, but the principle was not applied to extracorporeal circulation until 1956 The description by De Wall et al,[2] of a disposable bubble oxygenator coupled with the fixed-low-flow principle, developed in their cross-circulation work, has been followed by a series of modifications of the apparatus [3-6]

We record here some further modifications which have evolved in the course of our experimental [7 8] and clinical experiences and which have been dictated by the need for simplicity and economy

APPARATUS

In the original circuit[2] the venous blood was aspirated from the venæ cavæ directly to a 'Sigmamotor' pump With such aspiration, adherence of the caval walls to the orifices of the catheters often interfered with venous return We have got over this difficulty by using gravity drainage into a venous reservoir—which has incidentally simplified adjustment of the pumps during bypass We have found it possible to eliminate the venous pump and to rely on gravity to return the venous blood to the reservoir and thence to the oxygenator column The whole apparatus is lowered so that the top of the oxygenator column is below the level of the right atrium (fig 1)

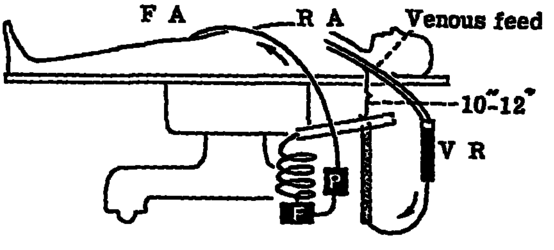

Fig 1—Showing the relation between the pump oxygenator and the patient

CARDIOPULMONARY BYPASS SURVIVAL EXPERIMENTS USING GRAVITY DRAINAGE AND ONE PUMP

Dog	Weight (kg)	Flow (ml per min)	Bypass (mins)	Blood-pressure (mm Hg)	Survival-time
1	11·5	1200	14		12 hours
2	13·0	1500	24	110	8 days (killed)
3	9·8	500	22	40–80	7 days (killed)
4	10·5	600	20	45–100	8 days (killed)
5	8·9	550	20	40–100	5 days (died)
6	9·0	600	20	40–90	12 hours
7	13·3	700	20	70	4 hours
8	9·9	530	20	40–90	6 days (killed)
9	9·0	450	20	60	7 days (killed)
10	9·7	500	20		6 days (killed)

Elimination of the venous pump removes a source of blood trauma

Under experimental conditions in our laboratory, a single T6S sigmamotor pump set at an output of 1 litre per minute, with a priming volume of 1 litre of dog blood, will produce 50–70 mg of free hæmoglobin per 100 g of blood after 1 hour With a priming volume of 2 litres, and a flow of 2 litres per minute for 1 hour, it will produce 200–250 mg

To reduce the blood damage we have substituted for the sigmamotor pump a commercially available British-made 'Mono' pump, which utilises the archemedian screw principle The use of this pump has a sound theoretical basis[9] and it has given excellent results in our hands (see table)

It gives a continuous flow of up to 6 litres per minute and can maintain a constant output against a head of pressure of 90 feet of water A standard production model B15 has been used, but sterile assembly of the unit has introduced some difficulties The manufacturers are now developing a unit which can be easily autoclaved and assembled At present the pump is driven by a $^1/_4$ h p single-phase 240-volt A C motor of 960 r p m through a Kopp 'Variator' to give a range of output from 700 to 5000 ml per minute

The coronary-sinus return is collected in an evacuated reservoir of conventional type maintained at a negative pressure of 3 cm of mercury by a separate suction pump From the bottom of this reservoir the blood is pumped by a hand-operated roller pump to the venous reservoir The circuit is primed by sucking filtered blood into the coronary-sinus reservoir and pumping it into the venous reservoir (fig 2)

The oxygenator column has an internal diameter of

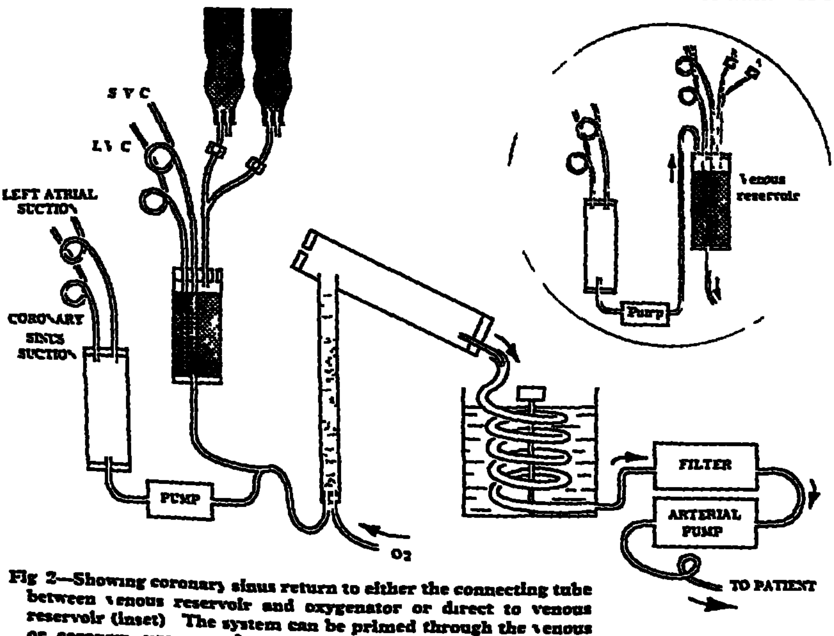

Fig 2—Showing coronary sinus return to either the connecting tube between venous reservoir and oxygenator or direct to venous reservoir (inset) The system can be primed through the venous or coronary-sinus reservoirs. The lead from coronary-sinus reservoir to external suction is not shown

$1^{1}/_{2}$ in and the tube connecting it to the venous reservoir has an internal diameter of $^{1}/_{8}$ in

RESULTS

This simplified circuit has been used on ten dogs and there have been seven survivors In the first experiment a filter was not used but in the remainder one has been incorporated in the base of the helix The amount of debris found on the filter at the end of each bypass has varied considerably, for no apparent reason In the sixth experiment there was insufficient blood to prime the circuit and the operating level in the helix was around 200 ml There should be at least 1 minute's flow volume in the helix to reduce the possibility of micro-bubbles being drawn into the arterial line The seventh dog died from a pulmonary embolus arising from the right atrial appendage A clamp had been applied to the appendage and two purse-string sutures inserted 20 minutes before heparin was given

The apparatus used in clinical cases has now been modified similarly Two patients (a tetralogy of Fallot and a ventricular septal defect) have been operated on using the modified oxygenator circuit and a single sigmamotor pump The patient in whom the ventricular septal defect was closed is alive and well The patient with tetralogy of Fallot died 24 hours after attempted complete correction Consciousness was regained and death is not attributed to the perfusion technique

DISCUSSION

Doubts have been expressed about the safety of bubble oxygenation,[10,11] but in view of its successful clinical application we decided to retain this technique while simplifying the circuit

The substitution of gravity drainage for pump suction immediately removed one of the main sources of anxiety during bypass While the venous pump was always carefully balanced against the arterial, frequent variations in the venous return necessitated continual adjustment of the venous pump With gravity drainage and elimination of the venous pump the circulation adjusts itself automatically and in a much shorter time

The hæmolysis caused by the sigmamotor pump, and its limited output, prompted the trial of the Mono pump which has a low hæmolysis factor, is cheaper, and is readily obtainable in this country Its range of output is adequate for all prospective bypass cases and its constant-flow delivery is a superior means of returning blood to a patient through a narrow cannula A pulsatile flow results in peaks of high pressure in the tubing between pump and patient at the top of the input stroke, and at the same time the jet injected through the cannula into the femoral artery gives rise to considerable turbulance All these factors must be harmful to the blood and seem unnecessary when one considers that at the site of oxygen exchange in the capillaries the pulsatile flow has been lost

SUMMARY

A simplified circuit for a bubble oxygenator is described Blood from the venæ cavæ is conducted to the base of the oxygenator by gravity, so that a venous pump is unnecessary For the arterial return a 'Mono' pump is used

We would like to acknowledge the cooperation of Mono Pumps Ltd, who supplied a pump for protracted trial, of Allspeeds Ltd (Oakenshaw Works, Clayton-Le-Moors, Accrington, Lancs), who provided a Kopp variator, and of the department of medical illustration, Guy's Hospital The two patients were operated on by Sir Russell Brock, whose continued support and encouragement have made this work possible

Reviews of Books

Doctor and Patient in Soviet Russia

Mark G Field, PH D, with a foreword by Paul D White, M D Cambridge, Mass Harvard University Press London Oxford University Press 1958 Pp 266 40s

Dr Field has spent only a month in Russia, but at the Russian Research Center at Harvard University he has made a long study of Soviet books and journals, has interviewed many doctors who have left Russia, and has analysed answers to a questionary addressed to 1650 former Soviet citizens His book is described as a study not of Soviet medicine but in the sociology of the medical profession, but as such it is the most penetrating commentary on medical Russia that we have seen Soviet medicine provides, he says, almost the extreme example of interference with the doctor's work Since the revolution Russia has been a mobilised society in which (as in war-time here) priorities at all levels have been laid down by the leaders Medicine had to be controlled in order that its practice should fit the aims of the regime, and, so long as the chief aim was intensive industrial production, doctors were under particular pressure in their certification of sickness The resistance of doctors to State pressure was weakened by abolishing their professional organisations, by indoctrination of students, and by reducing the doctor's prestige and standard of living Dr Field notes a striking resemblance between the position of doctors in Russia and that of schoolteachers in the U S A Admitting the advantages of central direction, he describes the harm done by red tape, and by the setting of " norms " in practice, and he also describes the gross differences in the kind of medical care given to different classes Yet, after forty years' vicissitudes the tradition of personal service has survived in the Russian doctor, comparing him with his German colleague, a refugee said that, though he has no complex equipment, he is " much warmer and more serious and, in the end, much better for the patient " Though, as Dr Field fully realises, the evidence of refugees from the U S S R will scarcely be unbiased, of 617 émigrés questioned in New York, 50% preferred Soviet medical arrangements and only 18% the American " In the Soviet Union ", said one, " the doctor is the slave of the State In America he is the slave of the dollar "

In many ways a formidable indictment of the Soviet system, this book is scrupulously fair

Advances in Virus Research

Vol 5 Editors K M Smith, virus research unit, Agricultural Research Council, Cambridge, M A Lauffer, department of biophysics, University of Pittsburgh, Pennsylvania New York Academic Press London Academic Books Pp 376 76s

The fifth volume is very much up to the standard set by its predecessors, and continues to provide authoritative reviews on different aspects of virus research The chapter by G S Stent on Mating in Reproduction of Bacterial Viruses is outstanding, and the synthesis of ideas presented in his review is likely to have a big influence on future research There are three good reviews on virus groups—J B Brooksby writes on foot-and-mouth disease, H A Wenner on the psittacosis group of viruses, and Ph L'Héritier on the hereditary virus of drosophila G Bertani tackles an important topic—lysogeny—in a stimulating way F Fulton writes authoritatively on complement fixation as applied to virology, and Anne Buzzell and M Hanig wrestle with influenza-virus hæmagglutination

LONDON 20 SEPTEMBER 1958

The Professional in Russia and China

In our type of western society, professions are important. Even when most of their members are working in State organisations, the professions remain independent of Government and continue to set their own standard, exerting their corporate influence not only in their own interest but in that of the public, as they see it. As a rule, work is better done by people who belong to a profession, accepting its restraints and responding to its ideals, and the present tendency of vocational groups to demand professional status should be encouraged as part of the natural development of our kind of community. But there is also, of course, a contrary tendency towards denigration of professions as no longer necessary or useful for people who have entered a "State service". Because of this, the professions could be seriously weakened even though structurally extant. There are warnings, perhaps, in the story of medicine in Soviet Russia, which has now well over 300,000 doctors but can be said to have hardly any medical profession at all.

In the book we review on p. 622 Dr Mark Field, of Harvard, describes the social history of the Soviet medical profession as "the history of the transformation of a self-conscious, independent, vocal, politically oriented, and militant corporate entity to that of a docile and politically inert employee group." The doctors of Tsarist Russia, "appalled by the poverty and the misery that surrounded them everywhere", were many of them ardent reformers, and after the February revolution of 1917 they began to put into practice plans by which medical care and public health would be financed publicly but controlled and supervised by the profession. But in October all such projects came to an end with the advent of the Bolsheviks, whose philosophy could not tolerate the exercise of power or influence by anyone other than the State. Step by step, the new Government abolished the professional organisations and deprived doctors of their corporate strength by putting them into a vast Medical Workers' Trade Union in which (though they have a section of their own) they were swamped by feldshers, nurses, and other ancillary medical personnel. The ancillaries, having belonged to the formerly "exploited" classes, were now encouraged to assume the leadership formerly claimed by the bourgeois-liberal doctors. Moreover, the medical trade-union was itself subordinate to the central committee of trade-unions, and since the early '30s this has been hardly more than an instrument of the Government. "Little trace", Field says, "was left of the medical profession as an organized, self-governing, social group or social force."

The "basic ethical universalism of medicine, which regards the sick individual as someone to be helped regardless of his station in life or class origins", was displaced, in the new Soviet medicine, by a "class" approach in medical care, as in housing, food, higher education, and other amenities, there was discrimination against people who were not party members or who did not belong to proletarian classes. Moreover, in a State which was on a war footing from its beginning, the interests of individual people came second to those of the community. Doctors should prevent disease, but, if they failed, they must at any rate do their utmost to prevent its interfering with production, and they were sometimes told that their first duty was to get as much work as possible out of their patients. Though this new sense of predominant duty to the community could scarcely be expected of people trained under the old regime, it was carefully inculcated into their successors, who now form the vast majority. Yet, strangely enough, the old medical tradition of personal service has survived. Despite official preference for workers' families, a high proportion of candidates for the medical schools come of middle-class parents who see in medicine a chance for their children to "help the people" without being directly involved with the regime or with politics.

Though no doubt most Russian doctors are generally in favour of the Socialist system which has modernised their country, Field produces evidence that less than a quarter are members of the Communist Party, and that most of these are administrators rather than clinicians. He speaks of a feeling among the others that party doctors "have somehow betrayed the profession by swearing allegiance to another group." He was told of a "sharp social split between party and non-party physicians, and that the latter tried as much as possible to avoid contact and involvement with the former even in professional matters."

Especially in former days, when labour legislation was more draconian, doctors concerned with certification of illness were exposed to severe strains: the authorities often expected them to put industrial production before health, whereas the patients expected them to be merciful and be their friends. With a style and standard of living little above that of most of the population, the doctor tended to identify himself with the patient and, as the "attorney of the poor", he was often able, by judicious use of the medical excuse, to "cushion and somewhat soften the impact of the system on the individual." Thus his work has become one of the adjustive mechanisms "that keep the social system going by reducing discontent, tension, and disaffection". Though the regime regard it as potentially dangerous because it escapes control, it is willing within limits to let him exercise his adjustive functions, and in fact "the physician's role of certification is a latent source of strength and flexibility in the system." It is an advantage to the regime that it has doctors who treat their patients as *their* patients—even at the risk of punishment. Similarly it is an advantage to the regime that, at the higher levels of medicine, some of the investigators have been less interested in official directives than in the progress of science outside their isolated country. There must be many who would agree with Field that "ideological controls imposed upon the medical profession add nothing to its efficiency, but rather detract from it by taking valuable time away from study and practice" Although (or perhaps because) there are no formal associations to band them together, there is a great deal of solidarity and cooperation among Russian doctors (other than party members), and now that political pressure on them has considerably abated, and international contacts seem rather easier, it will not be surprising if the profession regains some kind of corporate life

Whereas differences between Soviet Russia and other industrial nations seem to be steadily diminishing, the same may not be true of China The Russians began with a radically Communist revolution, but by successive concessions to expediency have achieved a national Socialist State now possibly in process of being liberalised The Chinese, learning by Russian experience, began with many compromises but now appear to be moving towards a more fundamental reorganisation of their society Among their compromises was the preservation of the Chinese Medical Association as the embodiment of the medical profession, and doctors from this and other countries who have visited China at the invitation of the Association have been heartened by finding that so many of its leading members have the same medical interests as themselves and apparently want to belong to the same medical world On the other hand, even last year, the issue was evidently in the balance The Chinese Medical Association has very close links with the Government, and official statements about the value of guidance by the Communist party have not been in line with Field's view (and ours) that "medicine, like other professions, is one in which the scientific approach must predominate and one which flourishes best in an atmosphere of free inquiry, scepticism, and the search for facts rather than doctrine, dogma, or political considerations" The Association's recent pronouncement on Anglo-American aggression in Arab countries [1] is depressing less because of its content than because it uses the stock phrases of Communist propaganda without so much as bothering to translate them into the more objective language more persuasive to doctors and scientists Even several years ago, when he made the observations recorded on p 633, Professor Gould formed the impression that in the Chinese struggle between science and dogma, science had already been defeated, and there is now more reason to fear that he is right If this fear is realised, however, we should still not make the mistake of underestimating what can be achieved by dogma, with technological aid, nor should we assume that what is thus achieved is necessarily inferior One of the greatest sociological experiments of our time, if not of all time, is beginning with the Chinese Government's new programme for dividing their population into huge communes in which men and women alike are to form a labour force disposable between the tasks of agriculture and industry [2] This scheme, which has the merit of avoiding the concentration of industry in cities with depopulation of the land, may take the Chinese much further towards Communism than the Russians have ever gone Beside so vast a social change, the loss of a profession, of professional ideals, and of the scientific attitude may seem a small one Nevertheless, in the long run, it would not be small at all

Fibrinolysin for Treatment of Blood-clots in Man

Blood-clots are not permanent structures, they may serve as a supporting framework for invading fibroblasts and capillary blood-vessels, but as these form new tissue the clot of fibrin disappears The process of getting rid of the fibrin—fibrinolysis—is now known to be brought about by a proteolytic enzyme and its precursors in blood tissues [1] The active fibrinolysin is named "plasmin", and this is present in blood in an inactive form called "plasminogen", plasminogen activators are present in blood, urine, and milk, trypsin can act as an activator There is also a system of proactivators, and one of the best-known of these is streptokinase Thromboembolism is still one of the serious causes of medical and surgical morbidity and mortality Once a clot has appeared, we prescribe anticoagulants in the hope of preventing further clots, and this indeed is the basis of the anticoagulant treatment of coronary thrombosis [2] But such treatment is like shutting the door after the horse has gone, tissue damage in the area blocked off by the original clot continues unchecked It would be better if we could remove the clot or recanalise the vessel as soon as possible, in addition to preventing extension or complication Accordingly attention has been given to fibrinolytic agents, and recent American reports suggest that a clinically useful fibrinolytic agent may have been prepared

Streptokinase was tested as a fibrinolytic agent [3], but streptokinase is not well tolerated and inhibitors were found commonly in blood Intravenous trypsin has been given a trial [4] it activates plasminogen and has some direct action on fibrin But here again there were snags antitryptic activity of plasma was found to be common, and the dose needed to produce an effect also interfered with other plasma-proteins, especially those concerned with blood coagulation Moser [5] has used a plasminogen prepared from the globulin fraction of human plasma-protein The plasminogen is activated to plasmin by streptokinase, which is subsequently removed, this active plasmin does not attack plasma-proteins other than fibrinogen and fibrin It had previously been shown [6] to remove clots produced experimentally in dogs and rabbits, and now Moser has reported on its use in 52 cases of thromboembolic disease in man, including 13 of cerebral thrombosis Lyophilised material was provided for clinical use, and it could be kept at −4°C for several months It was assayed in "fibrinolytic units", 1 F U is the amount of preparation which will change the turbidity of a standard fibrinogen-thrombin clot by 50% in ten minutes Clinical doses varied from 30,000 F U to 90,000 F U, the dose being increased as experience confirmed the safety of the substance, the lyophilised material was dissolved in 500-1000 ml of 5% dextrose solution and infused over two to four hours This material nearly always provoked a febrile reaction six to eight hours after the infusion, but any symptoms could be ameliorated by giving an anti-histamine drug, there was 1 case of generalised urticaria and 1 of local erythema There was no effect of any of the blood-coagulation tests Plasma-fibrinogen estimations showed that a small loss had occurred six hours after a dose of plasmin, but values were normal again in twenty-four hours There were no hæmorrhages even in patients having anticoagulant treatment. The fibrinolytic activity of the patient's plasma reached a maximum three hours after an infusion of plasmin; 30,000-50,000 F U raised the activity by 30%, and 70,000-90,000 F U produced a rise of 40%

[4] Taylor, A, Overman, R. S, Wright, I S *J Amer med Ass* 1954, 155, 347
[5] Moser, K M *ibid* 1958, 167, 1695
[6] Grossi, C E, Clifton, E E *Surgery*, 1955, 37, 791

The best results were obtained with peripheral venous thrombophlebitis and pulmonary embolism 18 patients with deep venous thrombophlebitis were treated, most of them showed loss of heat and tenderness and decreased swelling within twenty-four hours, and within seventy-two hours the affected part returned to normal, the phlebitis did not recur when the patient got out of bed, and pulmonary embolism did not occur after the treatment. Experience with 12 cases of peripheral arterial occlusion was less encouraging, no patient was certainly relieved Of 14 patients with cerebral arterial occlusion there was maintained improvement in 4, transient improvement in 3, and no effect in 7, MOSER considers that from this small group no definite conclusions can be reached, but there was no evidence that any patient deteriorated, and the infusions could be given with safety In coronary thrombosis not enough patients have yet been treated to decide whether fibrinolysin will be useful SUSSMAN and FITCH[7] used the same preparation of plasmin as MOSER for the treatment of 3 patients with cerebral arterial occlusion In 1, with occlusion of an anterior cerebral artery, there was no effect. In another, aged 75, with hypertension, a left carotid arteriogram showed occlusion of the internal carotid artery just beyond the bifurcation of the common carotid artery, infusions of plasmin into the left carotid artery produced some clearing, but there was no clinical improvement. In the 3rd patient, who had occlusion of the middle cerebral artery, the block was relieved after plasmin infusions and there was some clinical improvement.

These results suggest that it is worth obtaining further experience with plasmin preparations, especially in the treatment of superficial and deep thromboses of leg veins The results in cerebral vascular disease have so far been disappointing, but in this group of disorders we have so little effective treatment that even not very promising methods are worth testing We still need more information on toxicity and on dosage, and we need to know whether fibrinolysin treatment should be followed by anticoagulant treatment, and for how long The American workers used a plasmin preparation that was commercially available, and it should not be difficult for a similar preparation to be made in this country

Decline of the Father-image

THE increase in crime during the past few months is worrying everyone, and rightly so, for, however critical one may be of Home Office statistics, the present crime-wave must be accepted as real and disquieting Yet its cause remains as obscure as the cause of crime itself From a psychological standpoint, it is easy to agree that a defect in the super-ego plays a large part in inducing criminal behaviour, and to accept FREUD's thesis that the super-ego is formed by parental and other authority, and is the repository of morals, prohibitions, conscience —in fact, of the sense of right and wrong But it is less easy to define the super-ego precisely, and still harder to pick out the influences which determine its function for better or for worse

Recent studies of this problem include two investigations using the thematic apperception test and have provided some tentative information (The test consists in asking the subject to tell a story round each of a series of pictures showing situations of differing emotional flavour) In Australia LYLE and GILCHRIST[1] compared the results it gave in groups of delinquent and normal boys, and in the United States JENSEN[2] applied it to groups of boys showing extremes of aggression and passivity The amount of aggression shown by all the boys did not greatly differ, but delinquent and aggressively antisocial boys related stories of "naked" aggression, whereas the normal and the passive groups "buffered" their fantasies of violence with just retribution, suicide of the malefactor, and mitigating factors such as stealing for a starving family or acting under hypnosis Analysis of stories according to some other criteria showed, surprisingly, no significant differences among the groups Thus references to murder, robbery, intra-family tensions, feelings of rejection, love, and loyalty, were evenly distributed between the groups But socially taboo aspects of sex, violence, and language were more common in the stories of the antisocial boys The difference between the groups was not in aggressiveness itself, but in their social attitude towards it the antisocial groups showed a lack of guilt-reaction—a defect, in fact, of the super-ego

These studies still leave open the reasons for this psychological defect, and people tend to put forward unverified suggestions which vary according to the ethical, religious, social, or political tub which they happen to be thumping But the reasons lately put forward by GALDSTON[3] deserve careful consideration He lays the blame on the decline of the family, and particularly the change of orientation within it. Writing of the United States, he describes the cult of "momism" and suggests that American society has swung from a patnarchal to a "matriarchoid" pattern—if we may hesitatingly use his neologism Modern technology and social circumstances have emancipated the mother to the point where she no longer needs to bake the bread, weave the cloth, feed the chickens, and teach the children, nor does she (as the father must) earn the money She is free to build up a dominating position within the family, and to wreak havoc on the children by overprotecting them and ousting father as the principal figure As he says

[2] Jensen A R. Psychol Monogr 1957, 71, 13

[3] Galdston, I. Ment. Hyg 1958, 42, 229

> "The patriarchal family is rapidly disintegrating and in that process we are experiencing and witnessing a negation of those patterns, values and mores on which and by which our multi-millenial culture has been structured and buttressed Freud has taught us that the super-ego represents the introjected or incorporated father-image In the matriarchal family there is no conscionable father-image to introject"

GALDSTON's views on the matriarchy have some support from the GLUECKS' findings [4] that fathers of delinquents tend to be incompetent and lax in discipline Nearer home, the Metropolitan Police Commissioner [5] has reported a rise of 30%, during 1957, in young offenders between the ages of 17 and 21—many of whom, as war children, must have lacked even an incompetent father Those who agree with GALDSTON's observation that the structure of the family is changing may nevertheless be more cautious in laying responsibility for the change on the leisured mother During the Victorian age, for instance, thanks to maids rather than washing-machines, mothers of the middle classes probably had at least as much leisure as the mothers of today Yet paterfamilias retained his position as undisputed head of the family

However debatable this may be, few would disagree with GALDSTON when he points out that in the past the family was not merely a conglomeration of people but a working union Nowadays many of its duties and responsibilities have been taken over by other organisations, and the services for which the members of a family used to rely on each other have been reduced almost to vanishing-point Children, he reminds us, used to be an asset and from early years had their own useful place within the family But now they are regarded as a luxury, to be indulged in circumspectly They have no useful place, especially in urban life, and, save for their school work, have little to do and that little is of a "make-work" character

Nor does he neglect the importance of religion, surely the most super of super-ego forces The Church, he points out, was once the centre of art and culture, of music and community gatherings, of the healing and social services

> "Man is a creature that lives by values no less than by bread, and of late too many of his traditional values have been cast into doubt In the cataclysmic upheavals of two world wars, goodness, love, charity, mercy, truth, humility, brotherliness, have been violated and mocked There is current a highly organised, energetic and cunningly resourceful propaganda which makes the homely virtues and the religious persuasions and faiths of our fathers appear like a compound of neurotic anxiety, infantile delusions, political-economic naiveté and mean escapism Many who are caught in the tension field of this propaganda seek refuge in doctrinate bigotry, hence the resurgence of orthodoxy in morals and religion"

Much has been written about the so-called sick society (was it ever healthy?), and surely there can be no simple answer to the complex troubles of a complex civilisation Admittedly GALDSTON begs many questions (Would he, for instance, call English society *matriarchoid*?) But challenging views such as his are needed, if only to stimulate further social and anthropological studies A careful examination of the patient has long been held to be a useful prelude to effective treatment

---

Annotations

FAMILY DOCTORS AT WORK

SINCE 1948 a great many words have been spoken and written about general practice under the National Health Service, many of them, perhaps too many, have suggested that the standard of care is deteriorating and have depicted the general practitioner himself as overworked, underpaid, and ill-supported in his work When the present is difficult it is tempting and natural to recall the past with indulgence and regret, but in its day the past probably had its difficulties too, and before accepting criticisms of general practice it is worth considering how many are founded on opinion and how many on fact

Prof R M Titmuss, who takes a reasonably optimistic view of the family doctor's opportunities and progress within the administrative framework of the N H S, reminds us that some of its keenest critics have failed to make explicit the criteria they have in mind, and have avoided concrete comparisons with the conditions of the 'thirties Expressions of opinion are never easy to rebut, especially when there are few facts with which to challenge them Statistics and controlled observations about general practice are scanty and incomplete, but such as they are, in Professor Titmuss' view, they offer little support to the critics He has summarised the 15 available surveys in a useful appendix to his stimulating American lectures, which have now been published in this country [1] The most reliable evidence in his view comes from figures collected by the Ministry of Health and the British Medical Association, and according to them the quantity of the family doctor's work has not increased since the 'thirties In 1938–39 he gave each of his panel patients 5 10 items of service, in 1949–50 he gave each of his N H S patients 4 62 items These figures do not suggest that patients are making unreasonable demands on their doctors Indeed N H S patients might reasonably be expected to have needed more items of service, for, unlike the panel patients, they include vulnerable groups of children and old people, yet the number of items has actually fallen There are, however, no figures for the demands of private patients, and since the introduction of the N H S some of these are probably turning to their doctor more freely Among these patients the doctor's work may have increased Even so Professor Titmuss considers that the level of total demand has remained relatively low

In other ways he thinks that the doctor's work has been lightened The doctor is making more use of hospital outpatient facilities, and of the services of district nurses for injections and dressings. Doctors are also more evenly distributed over the country, many have arranged voluntary rotas, and night visiting is becoming rarer. Nor does the N.H.S. patient seem to need as many certificates as some suppose (48 per 100 N.H.S. patients in 1953–54, compared with 139 per 100 panel patients in 1938–39).

[5] Annual Report of the Metropolitan Police Commissioner, 1957 H.M Stationery Office

[1] Essays on 'The Welfare State" London George Allen & Unwin. 1958 Pp 232 20s

Quality is more difficult to assess than quantity, and standards of general practice cannot be judged on even the tenuous objective evidence available for quantity. But here, too, Professor Titmuss is unimpressed by over-facile jeremiads. The figures put before the Spens Committee, he reminds us, show that in the 'thirties too many practitioners were earning a miserable income, and in his view private practice was "less remunerative than most people were aware of then or imagine today." Most practices carried a burden of bad debts, and too many patients, oppressed by the cost, were reluctant to seek their doctor's help. Excellent as general practice often was, its benefits were often limited by accidents of wealth or locality, and families living in an industrial slum did not enjoy the same benefit as a family living in the village of Aysgarth.

His more buoyant assessment of general practice does not, however, mean that Professor Titmuss does not appreciate the problems that beset general practitioners today. He lays responsibility for many of these, however, not on the N.H.S., but on the impact of the physical sciences on medicine during the past forty years or so, and the increasing specialisation which these new complex techniques have demanded. Before 1948, Professor Titmuss points out, the general practitioner was usually a "singlehanded, professionally isolated, private entrepreneur." The more isolated the institution the greater the tenacity of custom and tradition, and Professor Titmuss suggests that his past isolation is partly the cause of the general practitioner's difficulty in adjusting himself easily to the swift technical changes in medicine and in accepting the necessity for greater reliance on the help of his colleagues.

Divided skills have unfortunately, but perhaps not unnaturally, brought divided loyalties, and Professor Titmuss would admit that these have been accentuated by the N.H.S., which has tended to centre the consultant services on the hospitals and to deprive the general practitioner of his place as the ultimate source of consultant practice. But if some aspects of the N.H.S. and of specialisation have tended to divide the profession and medicine, by fostering group practice and teamwork they are also potentially cohesive influences. Science has already offered the general practitioner effective new drugs, such as the antibiotics, which he can use in his own practice. The National Health Service has not only offered his patients care in hospital: it has also promoted the domiciliary services with whose help he can treat more of his patients in their homes. His growing preoccupation with early mental disease offers him new scope in preventive medicine. But these changes, though offering him new opportunities and more effective means of treatment, have destroyed some of his reliance on his personal interpretation of clinical experience, just as the growing knowledge and expectations of his patients have deprived him of some of his traditional unquestioned authority.

The National Health Service by providing an official whipping-boy has enfranchised complaints—from doctors and patients alike. But, as Professor Titmuss points out, many of these complaints are also made against private practice in the United States. In his view the true target is the changes in practice and the shifts in emphasis caused by "the eruption of science into medicine." The National Health Service is not responsible for these changes, and indeed in many ways is helping medical practice to assimilate them by providing a framework "through which medicine may more nearly fulfil its honoured purpose, the means by which the freedom of doctor and patient alike may be enlarged."

CORTISONE AND RECURRENT POLYNEUROPATHY

THERE is suggestive but not conclusive clinical evidence that in acute infective polyneuropathy of Guillain-Barre type cortisone may stop the rapid deterioration and may hasten recovery once deterioration has been stopped.[1 2] Austin,[3] of the University of Oregon, has described a remarkable case of recurrent polyneuropathy which indicates clearly that corticotrophin and cortisone were of value in treatment. A number of cases of recurrent polyneuropathy of unknown ætiology have been recorded since the first description by Targowla in 1894.[4] Typically the patient is a young adult who over many weeks or months develops a symmetrical, chiefly motor and distal, polyneuropathy, possibly with cranial-nerve involvement and an increased content of protein in the cerebrospinal fluid. Disability is greatest after four to five months, and the patient then begins to improve slowly and often recovers completely. After months or years of normal health a second attack occurs. In the 32 recorded cases reviewed by Austin the average number of attacks was three, and 4 patients died during an attack.

Austin's patient was a man, aged 40, who in five years had twenty attacks of polyneuropathy, and extensive investigation did not reveal the cause. The first attack became steadily worse for eight months, intramuscular corticotrophin halted the progress of the disease, this was followed by intravenous corticotrophin, improvement started within three days, and in two months he was without symptoms and was back at work. After being well for eleven months he had a similar attack with slow deterioration, and after three months he was severely disabled. Deterioration continued when he was given intravenous infusions of glucose and water as a placebo, but improvement started on the fourth day on which he was given an intravenous infusion containing corticotrophin. Studying this patient's recurrent attacks over five years, Austin found that there was a consistent, reproducible, and predictable pattern of response to corticotrophin, cortisone, prednisone, and placebos. Improvement began after the hormones were first given or the dosage was increased, bouts began after dosage was reduced, and on each of three occasions significant deterioration occurred during oral, intramuscular, or intravenous administration of placebos. There was a definite time-lag between the start of hormone administration and clinical improvement, this usually varied from five to seven days—a longer lag than in the acute symmetrical polyneuropathies, where two to three days is usual.

In this unique case the value of hormone treatment is clear, but, as Austin says, the hormones temporarily suppress clinical manifestations when the neuropathy is

4 Targowla, J *Rev neurol* 1894, 2, 465

active but do not cure the disease, and the patient now appears to be having continuous hormone treatment The mechanism by which cortisone acts in this case is by no means clear In 11 of the 32 reported cases of recurrent polyneuropathy that are reviewed, clinical enlargement of peripheral nerves was recorded In this patient's first two episodes, when there was a delay of three months or more before hormones were administered, enlarged firm nerves were felt, but in the later bouts, when hormones were given in the early stages, there was no clinical enlargement Biopsy of the left sural nerve in the second bout three weeks after corticotrophin had been started showed mild to moderate interstitial and subperineural œdema Austin does not consider that the dysfunction in the peripheral neurones was due to a compressive effect of this interstitial œdema, and he suggests that the œdema is due to distended capillary and cell-membrane permeability and that this might seriously affect fluid-electrolyte distribution and other metabolic functions of the axone-myelin-Schwann cell complex with resulting impairment of function

ESCHERICHIA COLI IN FARM ANIMALS

Escherichia coli was long suspected in an indeterminate way of causing diarrhœal diseases in man and animals, but conviction had to await the work of Kauffmann in subdividing this universal species into types or subspecies by serological methods It is now well known that some of these types may be associated with acute diarrhœa in infants both the clinical picture and the pathological changes in bowel and kidneys are fairly characteristic The evidence that these types are the " cause " (in the sense that *Salmonella typhi* is the cause of enteric fever) is suggestive The organism is present in the bowel at the acute stage of the disease in almost pure culture, and it disappears in convalescence The disease produces specific antibodies in the blood and has been reproduced experimentally In certain children's hospitals the disease has behaved as an extremely infectious specific fever, and methods of control based on this thesis have had some moderate success The pathogenic types of *Esch coli* have, however, been found quite frequently not only in adults but in healthy infants congregated in institutions An epidemic is due to a single type, but within an institution this type may for no obvious reason disappear or be replaced by another type Some types (e g, 0 111 B 4) which did most damage ten years ago are nowadays almost extinct

Certain serological types of *Esch coli* have been identified as the cause of scours in calves, and, as in man, the types responsible have changed over a period of years (With one or two exceptions the types pathogenic to calves have so far been harmless to infants) Because calves can be observed experimentally, we know rather more about the epidemiology of their disease [1] than that in babies Maternal antibodies transmitted in the colostrum normally give a high degree of protection, but if the calf is brought into contact with pathogenic types of *Esch coli* antibodies to which are not present in the colostrum it will probably die This is borne out in practice by the experience that it is unwise to move a calf to a fresh environment in the first few days of life or even to move the cow shortly before the calf is born The protection given by colostral antibodies is not absolute an overwhelming infection by a virulent type will sometimes swamp the defences

" Gut œdema " has been known for many years as a serious disease of pigs, and is usually ascribed to dietary indiscretion The name is apt, but the œdema may affect other parts postmortem appearances are not unlike those in some cases of " coli enteritis " in infants New light has been thrown on the ætiology of this disease by the observation that in almost every case *Esch coli* of one of four specific serological types are present in the bowel and mesenteric glands, and that the disease can be reproduced by the intravenous injection of an extract of one of these types [2] There is also some evidence that a specific antiserum may benefit some infected animals Of the epidemiology of this disease we are still rather ignorant Most commonly it attacks store pigs of 10–14 weeks but it may occur in younger animals It does not seem to have the characters of an acutely infectious fever, but traditionally its onset follows a change of housing or of diet To confuse the inquiring veterinarian there arises in young piglets an apparently distinct diarrhœal disease which seems to be akin to scours in calves, the types of *Esch coli* responsible for this are distinct from those associated with gut œdema

These diseases of man and animals have many likenesses but also some obvious differences In each case there are reasonable grounds for believing that the observed pathological changes are due to toxins produced by specific types of *Esch coli* (Although one or two of the types causing scours have been found in infants it is generally true that each disease is associated with its peculiar specific types) It also seems clear that the types which cause infantile enteritis and scours are not invariably pathogenic In this connection Lovell has suggested that the soil is as important as the seed, and by his own work has demonstrated the importance of immunity acquired from the mother Babies, of course, get their maternal antibodies through the placenta, and there is no evidence, so far as we know, that these play any part in protecting the infant against enteritis due to *Esch coli* A change of environment (which means, probably, contact with alien types of *Esch coli*) seems to be of real importance in precipitating these diseases among animals Its danger in man is less easy to establish Because we live in relatively isolated families, diarrhœal diseases of infants are likely to be seen in epidemic form mainly in institutions, but, in fact, single infections in the home and in the communal nursery are not uncommon

There is one other factor which tangles further an unruly skein Beyond much doubt there are diarrhœal diseases of man and animals due to filterable agents [3,4] In man these are highly infectious but less severe than those due to *Esch coli* On the analogy of hog cholera, a viral disease almost always complicated by infection with *Salmonella choleræ-suis*, the suggestion has been made that all these enteric diseases of young animals are primarily due to infection with one or more viruses but are complicated and perhaps made more severe by the specific types of *Esch coli*

These diseases are receiving much attention, and on economic grounds alone they deserve it Our knowledge of the comparative morbid anatomy is scanty Observations in the field and the hospital have been often disjointed and unplanned The methods of experimental epidemiology which have been so fruitful in the calf can be applied to pigs and even, in part, to man

MINAMATA DISEASE

AN UNUSUAL NEUROLOGICAL DISORDER CAUSED BY CONTAMINATED FISH

DOUGLAS MCALPINE *
M.D Glasg , F R.C.P
SHUKURO ARAKI
M.D Kumamoto

From the Department of Neuropsychiatry, the Medical School, Kumamoto University, Kyushu, Japan

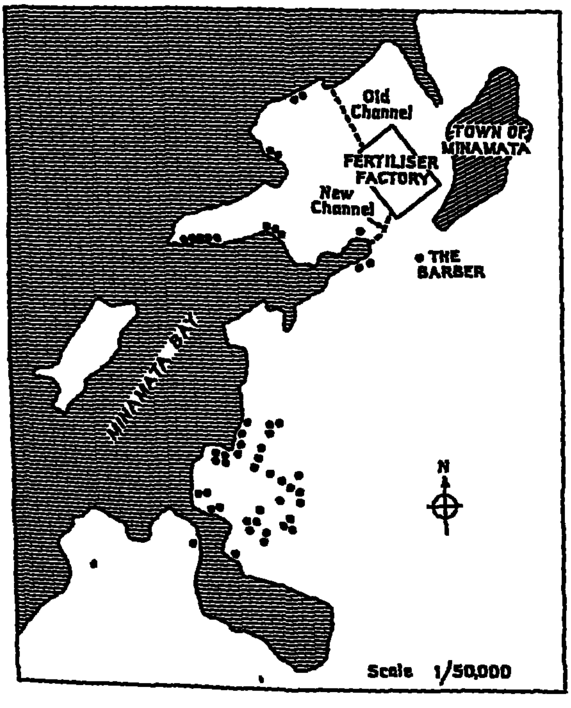
Minamata is a small industrial town near the south-west coast of Kyushu, the most southerly of the main Japanese islands The chief industry is provided by a large artificial-fertiliser factory, the effluent from which empties into Minamata Bay A number of villages are located on or near this bay, mainly to the north and the south. The short coastline opposite the middle of the bay is uninhabited (see figure)

From the end of 1953 a mysterious nervous illness began to affect the villagers near the bay, and by 1956 it had assumed epidemic proportions The outbreak was investigated by a number of departments of Kumamoto University and the results were published last year in the *Kumamoto Medical Journal* (Kitamura et al 1957)

Clinical Features

During 1956, 15 cases (9 adults and 6 children) were admitted to Kumamoto University Hospital

The onset of illness was acute or subacute and usually unattended by fever or constitutional symptoms In all the adults numbness developed in the extremities and sometimes around the mouth, often accompanied or followed by slurred speech, unsteady gait, and increasing disability Most of the patients complained of deafness and disturbance of vision, the latter being associated with generalised constriction of the fields Dysphagia and increased salivation were less commonly observed Insomnia was a striking feature in 3 adults and 2 children 6 adults showed emotional lability in the form of euphoria or depression The seriously ill patients were mentally confused, drowsiness and stupor alternated with periods of restlessness and shouting Cerebellar ataxia and dysarthria were always present, but nystagmus was noted in only 1 patient Choreiform or athetotic movements were observed in several adults, and hemiballismus in 1 The deep reflexes were exaggerated in 4 patients and depressed in 2, an extensor plantar response was noted twice Distal hypæsthesia was found in the limbs of 3 adults, but in reports no mention was made of vibration or postural senses Epileptiform attacks occurred in 1 child and 1 adult during the period of observation.



Based on a map published by the public-health department of Kumamoto University to illustrate the distribution of 52 cases of Minamata disease

4 adults showed a mild degree of secondary anæmia The cerebrospinal fluid was normal except for a moderate pleocytosis in 1 patient The serum showed an increase of gamma-globulin. An abnormal amount of aminoacids was found in the urine of the more seriously ill adult patients Estimation of serum-copper was normal, manganese was found in excess in 1 case

The course of the disease fluctuated and its results were variable, the most severely affected died, while others remained incapacitated in varying degree. Improvement in hospital was occasionally followed by relapse on returning home

Pathology

The brain and certain internal organs from 4 patients, and one spinal cord, were available for study

Apart from small areas of necrosis in the intestinal mucous membrane, and scattered areas of necrosis in the liver in 1 case, there was no abnormality of the viscera The main findings in the central nervous system were (1) cell degeneration, which was most marked in the granular layer of the cerebellum, while changes of varying degree were apparent in the basal ganglia, hypothalamus, midbrain, and cortex, (2) dilatation of the perivascular spaces, with occasional softening, but no true demyelination, (3) œdema and occasional small hæmorrhages, and (4) reactive gliosis The spinal cord showed minor changes, the anterior-horn cells were unaffected

Epidemiology

The public-health department of Kumamoto University reported 52 patients, all of whom frequently ate fish from Minamata Bay There were 39 cases in four villages with a total population of 2091, giving a morbidity-rate of 19 per 1000 population The remaining 13 were scattered over seven districts with a population of 7988, giving an overall rate of about 5 per 1000

The figure shows that with one exception, namely a barber living on the outskirts of Minamata Town who fished in his spare time, all the cases occurred in the neighbourhood of the bay The patients were distributed among 40 families In 36 (90%) of these at least one member fished in the bay, but in 48 (71%) of 68 neighbouring families who were unaffected no-one fished. 25 of the 40 affected families every day ate fish or shellfish which came from the bay, and the remaining 15 consumed fish from the bay two or three times a week. By contrast, only 5 of the 68 unaffected families were in the habit of eating fish daily from the bay, and most of them ate less fish per week than the affected families Of 31 males and 21 females who became ill, 10 were children under the age of ten, but no infants were affected By December, 1956, a further 4 cases had been reported. Of the original 52 patients, only 3 were able to return to work within 6 months, 9 improved, and 23 were stationary, there were 17 deaths This gave a case-mortality of 33% 8 patients died within 2 months and 4 within a year

---

* Present address Institute of Clinical Research, Middlesex Hospital, London, W 1

Fishing in Minamata Bay was mainly carried out at night; on returning home in the morning the fishermen and their families usually ate raw the freshly caught fish. But the survey of the public-health department showed that cooked as well as raw fish can cause the disease, which suggests that the toxic substance is thermostable. Those who ate fish for breakfast seemed likely to consume more daily than the schoolchildren who left home before the morning catch had been brought in; this may account for the escape of several children of families in which other members were affected.

A Disease in Animals

A disease also appeared in animals which had eaten fish or shellfish.

In the 40 affected families there were 61 cats and 50 died between 1953 and 1956, sometimes in as little as 2 days. Unsteadiness, frequent falls, circling movements, and convulsions were observed; forced running appears to have caused some of them to enter the sea and be drowned. The 68 unaffected families owned 60 cats and of these 24 died. 5 pigs and 1 dog died, also many crows which were in the habit of settling on a floating landing-stage where the returning fishermen tied up. The brains of 10 cats were examined; the changes were similar to those observed in the human material, the granular layer of the cerebellum being especially affected. The disease could be readily produced experimentally in cats by feeding them for 2 to 4 weeks with fish from Minamata Bay.

Chemical Investigations

The chemical investigations were difficult to evaluate since several departments carried out independent analyses of human and cat material, and of fish from the bay, with varying results, but the following appear relevant.

(1) Some fish and shellfish from the bay showed increased amounts of manganese, selenium, and copper as compared with controls from another area, while the amounts of thallium, arsenic, lead, and iron were not significantly raised.

(2) The silt from that part of the bay into which the effluent from the fertiliser factory flowed was dark in colour, mudlike in consistence, and contained sulphur and a toxic sulphur derivative, mercaptan (ethane-thiol). Large amounts of selenium, and smaller amounts of manganese, thallium, copper, lead, and iron were also found in the silt, all were increased as compared with the analysis of sand from another part of the coast.

(3) Selenium was present in human and cat livers in roughly the same proportion as reported in cases of selenium intoxication, and manganese was found in the hair of the affected cats.

(4) The raw material used by the factory contained, inter alia, thallium and selenium.

(5) In 1953 the principal products of the factory were ammonium sulphate, ammonium and calcium phosphate, sulphuric acid, carbide, and nylon.

It was concluded that the outbreak had been caused by a toxic factor in fish but there was no agreement as to its nature.

Personal Observations

During two visits to Minamata in February and March, 1958, we had the opportunity of examining 16 patients in their homes, and 6 others in Kumamoto University Hospital.

Multiple cases occurred in 3 families.

Egoshita family.—During 1956 both parents and 2 sons (aged eleven and nine) noticed mild peripheral numbness, dysarthria, and ataxia, but they all gradually recovered over a period of several months; a daughter (aged five) developed dysphagia in addition, and died in hospital of aspiration pneumonia. 1 other older son living at home was not affected.

Kaneko family.—The father became ill with dysarthria, tremor, and ataxia during 1954; his condition slowly deteriorated and he died in June, 1955. Also during 1954, the elder son (aged five) developed similar symptoms associated with spastic weakness of the left leg, but he gradually improved after a few months. The younger son had a severe attack of measles in 1956, when eight months old, and afterwards failed to sit up, talk, or walk. But he was entirely breast-fed until after the age of two—which makes the diagnosis of Minamata disease unlikely, since the mother remained well throughout.

Tanaka family.—In March, 1956, a child of six was febrile for 1 day, and during the next 2 or 3 weeks developed progressive ataxia, dysarthria, dysphagia, and visual deterioration. In April she became agitated and had a generalised convulsion; nasal feeding was necessary and she was admitted to hospital. In February, 1958, she was mute, deaf, and apparently mentally defective. She could not sit up though she was able to see large objects. The pupils and fundi were normal; all four limbs were flexed and spastic. A younger sister (aged three) developed progressive dysarthria and ataxia in April, 1956, and later dysphagia and incontinence. When seen by us she was mute and unable to sit up, though she could move all her limbs freely. The optic discs were normal, the deep reflexes were exaggerated, and the plantar responses equivocal. The mother was normal, but no details are available of the rest of the family. (The history of these 2 sisters was taken from notes published in the *Kumamoto Medical Journal*—pædiatric department, cases 1 and 6—in 1957.)

Discussion

The salient facts regarding this unusual outbreak seem reasonably clear. In a scattered community, living near the sea, there appeared an obscure neurological illness which assumed epidemic proportions within 2 years, causing death in more than a third of its victims and serious disability in most of those who survived. Concurrently, a fatal illness affected domestic animals and also scavenging crows and fish in a nearby bay. Two facts were established—firstly, that there existed a close relationship between the eating of fish and the occurrence of the disease, and, secondly, that the fish responsible for the outbreak had been caught in Minamata Bay. This last observation was supported by the results of a ban placed on fishing in the bay which came into operation in November, 1956, since when no fresh case has been reported. Chemical analysis of silt from the bay suggested that the water was polluted by effluent from a fertiliser factory. Inquiry showed that the factory introduced no new process in 3 years before the outbreak. Professor Kitamura, however, pointed out that until 1950 the effluent was diverted into the open sea by a channel to the north of the factory, but in 1950 this was closed and a new one constructed which runs directly to Minamata Bay (see figure).

Clinically, the subacute onset of numbness in the distal portion of the limbs and occasionally around the mouth suggested peripheral nerve involvement. In a few patients the numbness became generalised and was accompanied by sensory ataxia, recalling the so-called "sensory neuropathy", in which posterior-root ganglia are primarily affected, usually as a complication of carcinoma (Denny-Brown 1948, Henson, Russell, and Wilkinson 1954). Cerebellar symptoms were conspicuous at the onset but nystagmus was a rare finding. Not infrequently there was deafness and disturbance of vision; in the few cases in which perimetry was performed the visual fields were generally constricted. With one exception, the optic discs were normal in patients examined 2 or 3 years after the onset. Pyramidal signs were occasionally found. In the more seriously ill patients there were symptoms of an encephalopathy—i e , mental confusion, stupor or coma (in the fatal cases), convulsions, involuntary movements of varying type, and insomnia In some, the presence of intellectual deterioration, mutism, epilepsy of late onset, an increasing degree of limb spasticity, and incontinence suggested a form of progressive neuronal degeneration Involuntary movements were occasionally prominent in the early stages, but we did not observe parkinsonism or choreoathetosis as a sequel, though, in one case, there was a striking tremor of the red nucleus type

There seems to be a fair measure of agreement between the clinical and pathological findings as to the anatomical localisation of the disease, but the ætiological factor is uncertain. In the published reports on Minamata disease no mention is made of gastrointestinal symptoms, but the possibility that a toxic metallic compound was responsible for the outbreak is supported by the occasional complaint of increased salivation and by the finding of areas of intestinal necrosis in each of the 4 patients who came to necropsy

Some of the neurological features of Minamata disease have been observed in toxic states due to certain metals

Methyl mercury compounds may cause ataxia, dysarthria, constriction of the visual fields, an occasional extensor plantar response, and, experimentally, peripheral neuritis and degeneration in the granular layer of the cerebellum (Hunter, Bomford, and Russell 1940) Thallium may cause a complex neurological picture—i e , psychosis, choreiform movements, inversion of sleep rhythm, deafness, retrobulbar neuritis with optic atrophy, ocular pareses, bulbar palsy, pyramidal signs, and peripheral neuritis In severe cases convulsions may be followed by coma and death (Prick, Smitt, and Muller 1955) In carbon-disulphide intoxication manic-depressive psychosis and mental confusion may be prominent, while peripheral neuritis, disturbance of vision, optic atrophy, deafness, and, in the chronic stage, parkinsonism may occur Manganese mainly affects the basal ganglia, resulting in a variety of striatal symptoms, including parkinsonism. Mild psychiatric symptoms have been attributed to chronic intoxication with selenium (Lemley and Merryman 1941), but we have been unable to find reference to neurological manifestations

Degeneration in the granular layer of the cerebellum, a conspicuous feature of Minamata disease, is non-specific, having been found in various pathological conditions such as anoxia, hyperglycæmia, hypoglycæmia, mercury intoxication (bichloride and methyl compounds), and chronic alcoholism (Leigh and Meyer 1949, Neuberger 1957)

Of the three metals manganese, selenium, and thallium, which have received most attention from those investigating the disease, only the last-named seems likely to produce on the nervous system an effect similar to Minamata disease It is hoped that the results of work which continues in Kumamoto University may throw light on the nature of the toxic agent responsible for this unusual outbreak.

Summary

The clinical, pathological, and epidemiological features are described of an unusual neurological illness which, between 1953 and 1956, attacked villagers living near Minamata Bay in Kyushu Island, Japan

Characteristically the disease affects the peripheral nervous system, the cerebellum, hearing and vision, and less frequently the pyramidal tracts In severe cases an encephalopathy may be followed by signs suggesting progressive brain damage

The pathological findings are widespread neuronal degeneration, particularly in the granular layer of the cerebellum, and areas of intestinal necrosis

Fishermen and their families were mainly affected and the evidence suggests that the disease was caused by eating fish caught in Minamata Bay

Concurrently a disease associated with ataxia and convulsions proved fatal among domestic animals, especially those belonging to affected families, and also among scavenging crows

Although the cause is not yet established, the evidence so far points to the toxic action of an inorganic chemical compound contained in the effluent which flowed into Minamata Bay from a nearby fertiliser factory

We would like to acknowledge grants received from the National Institute for Neurological Diseases and Blindness Bethesda 14, Maryland, and to thank Prof R Miyagawa who afforded us facilities for this study.

U F A W

(The Universities Federation for Animal Welfare)

THE medical profession exists for a purpose which is essentially humanitarian, and the humane mentality which belongs to it may be expected to extend beyond the human species to the other animals, which are, so to speak, man's poor relations But the practical expression of this interspecific sympathy, which is a logical development of man's intraspecific social conscience, has been hindered during the past three-quarters of a century by the controversy about vivisection, and in lesser degree by other propaganda inspired by a love of animals but conducted in an over-emotional way which is repugnant to the scientific mind

There is, however, one animal-welfare society which provides a channel through which medical men can safely give effect to their sympathy for animals without compromising their intellectual integrity The policy of UFAW is determined by a board of directors who are elected by the ordinary members, and these are required to have a university or professional qualification Although a university education is not an infallible guarantee of soundness of judgment, this arrangement has in practice proved a sufficient safeguard against the influence of extremists Moreover UFAW has found it necessary to rely largely on veterinarians and zoologists for practical guidance, thus ensuring a sound factual basis for its policies

Its president is Dr Edward Hindle, F R.S , sometime regius professor of zoology at Glasgow, its scientific advisory committee is composed largely of research scientists, under the chairmanship of Prof P B Medawar, F R.S , the president of its veterinary section is Prof W I B Beveridge, of the Cambridge Veterinary School, its technical secretary is a medical woman, Miss Jean Vinter, M D , and its founder and secretary-general, Major C W. Hume, is a physicist with an amateur interest in biology.

LABORATORY ANIMALS

Most of the other animal-welfare societies in the British Isles are committed to an antivivisectionist policy, though two or three leave the subject entirely alone UFAW is the only one which has developed a positive and constructive policy in this connection

The UFAW Handbook on the Care and Management of Laboratory Animals, now recognised as the standard textbook on its subject, was first published in 1947, and, in conjunction with the Laboratory Animals Bureau (now Centre) of the Medical Research Council and the Animal Technicians Association, has been responsible during the past decade for a vast improvement in the comfort as well as the usefulness of laboratory animals

The editor of the first edition was A N Worden, some time Milford professor of animal health at Aberystwyth and, in his student days, chairman of the students' committee of UFAW The second edition, edited jointly by A N Worden and Dr W Lane-Petter and recently published, had to be so much enlarged that the original publishers were unwilling to publish it, although, at the same time, they were unwilling to relinquish the copyright UFAW therefore had to buy the latter for a sum which will entail a financial loss on the whole transaction, but the object has been to provide information rather than to make a commercial profit

More recently UFAW has turned its attention to laboratory techniques, on which it maintains a research team A symposium last year on Humane Technique in the Laboratory was attended by about 120 research scientists A brief report was published in this journal [1] and most of the papers have been published by the Laboratory Animals Centre as vol 6 of its *Collected Papers* UFAW hopes, in the first place, to see an acceleration of the replacement of animals by unconscious material in tests such as the determination of an L D 50 or an E D 50, which at present entail discomfort For instance, UFAW is sponsoring a research which is being directed by Dr Michael Chance in the medical school at Birmingham and which might, if successful, enable a wide range of such tests to be replaced by one using mice which are anæsthetised and are killed before they recover consciousness A second hope is a reduction in the number of animals needed for a given degree of precision,[2] effected either by statistical techniques, or by genetical homogeneity of response to experimental treatments, or by detection of specific factors which effect variance On the last point, UFAW is sponsoring a research directed again by Dr Chance in Birmingham (The last-mentioned research, incidentally, inaugurates a long-overdue study of the psychology of laboratory animals) A third hope relates to refinement of laboratory techniques for the purpose of reducing or eliminating discomfort As a contribution to this aim a UFAW research fellow, Dr Phyllis Croft, is carrying out electroencephalographic studies of anæsthetics and relaxants in Professor Amoroso's laboratory at the Royal Veterinary College A comprehensive review of the whole problem has been written by Dr W M S Russell, a UFAW Research Fellow, and will be published shortly by Messrs Methuen with the title *The Principles of Humane Laboratory Technique*

WILD AND DOMESTIC ANIMALS

But the laboratory animals are only one, and a comparatively recent one, of UFAW's interests

The gin trap was scathingly condemned for its cruelty by several of those who spoke in defence of research when the Cruelty to Animals Act, 1876, which regulates vivisection, was passed through Parliament in 1876, yet it was finally outlawed no longer ago than July of the present year, as a result of a long campaign An important factor in this success was a four-years' research on the ecology of the wild rabbit which was sponsored by UFAW and for which two M SC degrees were awarded

Again, during a great many years some scores of thousands of unwanted dogs were killed annually by animal-welfare societies by passing electric current between the neck and the hindquarters, and strong opposition was offered, on antivivisectionist grounds, to UFAW's demand for a scientific investigation of the process Eventually it became possible for Dr Phyllis Croft, a UFAW research fellow, to make this investigation, whereupon the British Veterinary Association instituted an independent research which confirmed her finding that, in spite of superficial appearances, excruciating pain was being caused to each animal for about 12 seconds, and that this could be avoided by passing a sufficient current through the brain For this work Dr Croft was awarded the Livesey medal of the Royal College of Veterinary Surgeons

Another research sponsored by UFAW is one relating to humane poisons for wild rats and directed by A N Worden at the Nutritional Research Centre, Huntingdon

Again, at the suggestion of a member of the Home Office Committee on Cruelty to Wild Animals, UFAW called together and administered a committee representing zoologists, sportsmen, and others interested in the otter A research on the ecology of this animal was undertaken with funds contributed mainly by the Nature Conservancy and to a much smaller extent by UFAW, and it is interesting to know that, although this had to be discontinued for lack of funds after two years, within a fortnight of receiving the published report the Prime Minister of Denmark made an order protecting the otter in that country

Some time ago Prof W I B Beveridge called UFAW's attention to the painful disease of foot-rot in sheep, which is very widespread but can be eradicated if certain fully practicable steps are taken With the support of the British Veterinary Association, the British Wool Marketing Board, the National Sheep Breeders' Association, and the National Farmers' Union, UFAW has been conducting an educational campaign on the subject, and is now sponsoring the production of a film which shows technical details of the requisite treatment

THE NEED FOR SUPPORT

UFAW draws its funds partly from the sale of publications (and especially of Christmas cards designed by its honorary artist and chairman, Fougasse) but mainly from voluntary subscriptions and legacies In the latter respect it is at a disadvantage in being precluded from making appeals of the sensational type, which alone open the more lavish purses If it were to become an antivivisection society its financial worries would disappear overnight, but on the other hand its ability to perform its special function would be destroyed It has therefore to rely on subscribers who are both generous and intelligent, and these are not so numerous and wealthy as could be wished

UFAW's primary function is to create or obtain authentic information bearing upon the welfare of animals and to convey this to those who can use it to advantage, including the general public in the case of the less specialised information To this end it is necessary to recruit support among university students, who are the professional men and women of the future, and at present there are branches in ten British universities It is disappointing, however, that there is no organised branch in any of the medical schools, and that the number of qualified medical supporters, though by no means negligible, is small in proportion to the size of the profession

The Wider World

GALEN IN CHINA

DONALD GOULD
B Sc. Lond., M.R.C.S , D T.M. & H.
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF MALAYA

IN December, 1955, I visited China and saw something of the costly, strong, official drive to boost traditional remedies and practice Nothing in the medical scene impressed me more, and like Fox[1] I came away feeling that political rather than scientific motives lie behind it Under Communism, of course, all activities are supposed to contribute to the construction of the socialist State, and to this extent every movement in a 'Communist country is bound to demonstrate, or at least pretend, a political element. Yet it is none the less disturbing to find a naturally non-political field like that of therapeutics the subject of a determined political assault. Men trained in Western medicine are being forced to accept and adopt ancient magics

One medical official I met early in my trip said that traditional practitioners were being given elementary instruction in health rules, and were being taught to undertake certain tasks such as vaccinations and simple treatments He pointed out that there is still a grave shortage of Western-trained doctors, that the traditional practitioner is the village doctor of China, the man the people know and trust, and that therefore traditional doctors are being employed for certain urgent and widescale medical activities I was left with the impression that these men are being put to good use until they can be replaced by the products of the medical schools Since China has some 600 million people, about half-a-million traditional practitioners, and only some 70,000 doctors trained in Western methods, this seemed a wise course

But I found later that the accent was not upon using the traditional doctor as a medical auxiliary, not upon encouraging the old to accept the new, but upon forcing acceptance, approval, and admiration of the whole established rigmarole of native therapy In an article entitled "Why Our Western-Trained Doctors Should Learn Traditional Chinese Medicine", Dr Fu Lien-Chang[2] president of the Chinese Medical Association, wrote

> "How many western-trained doctors since Liberation have studied Chinese medicine and have obtained successful results? Very few indeed! The great majority of western-trained doctors have never considered the learning of traditional medicine as a task that should be undertaken seriously The responsibility for this state of affairs lies with the health administration and the Chinese Medical Association for not having carried out their task of leadership
>
> "Take myself for example Although I have attended patients with practitioners of our native medicine, I have never considered Chinese medicine as a subject I should learn I have never seriously studied any books on traditional medicine Hence, even today, I remain a complete ignoramus as far as our native medicine is concerned. As a leader in our country's health work and as Head of the Chinese Medical Association, I am ashamed to confess this I must seriously take up the study of Chinese medicine."

And later

> "In the past we have organised training courses for old-time physicians to learn western medicine. This, although necessary, is *not of the greatest importance* The Central Committee of the Party and Chairman Mao have enjoined us that the key to the problem is that our western-trained doctors should study traditional Chinese medicine It must be emphatically stated that not only should doctors of traditional medicine learn western medicine but, particularly, western-trained doctors should study Chinese medicine"

Dr Fu leaves no doubt about the direction of the effort demanded Nor is doubt left after visits, in Peking, to the Institute for Research into Herbal Medicine and the Institute for Research into Acupuncture.

THE INSTITUTES

These institutes are ill named They are not research laboratories, but propaganda bureaus

Acupuncture

The Acupuncture Institute, housed in a former Buddhist monastery, devotes the better part of its space to an exhibition.

The public come daily in organised groups The tour, conducted by a hard-talking guide, takes nearly an hour A brief account of three of the exhibits will show the tone of the place

> A placard states that "This summer one acupuncture doctor cured 250 patients at a total cost of $12.50 By orthodox treatment, 35 similar patients would cost $339 50 to cure On an average, each case took 1 12 days By Western methods, each would have taken 3.5 days"
>
> A map of the world has a gleaming acupuncture needle overlying China From this needle radiate ribands to all the other countries which have accepted and adopted acupuncture—among which England, Canada, and the United States are included
>
> A show case holds envelopes addressed to the institute and bearing a variety of foreign stamps They are evidence of the unsolicited testimonials which arrive daily from all quarters of the globe.

These are fair samples from a large collection of manuscripts, photographs, impedimenta, and charts, all designed to convince the layman that acupuncture is and always has been a very good *thing, and that Western medicine comes a poor* second

Graphs and histograms abound. There are X-ray photographs Statistics are worked to two decimal figures The grubby old magic is given a fine, new, white laboratory gown.

As well as the exhibition, the institute houses "research departments" (one department, one room) of physiology, biochemistry, metabolism, pathology, bacteriology, and statistics (I am not quite sure of this last title, but it was the best I could make of the description given to me) When I was there, "research" was not yet fully under way, but the purpose of the "research departments" was clearly that of providing "scientific proof" for acupuncture's claims

Finally, and perhaps most importantly, the institute is a training school Doctors already trained in Western medicine are given an intensive course so that they may go back to the medical schools as teachers

Herbal Medicine

At the Institute for Research into Herbal Medicine, a more sober tone prevails The native practitioner who dispenses the remedies of the Chinese pharmacopoeia is very like his Western counterpart of a hundred and fifty years ago The pretence to equality with Western medicine is therefore more easily sustained, and there is not so much need for vigorous demonstration of superiority and "scientific worth"

The institute is run like any Western clinic. There are consulting-rooms and there are laboratories and there are lecture rooms, and the traditional doctors on the staff wear long white coats and carry stethoscopes round their necks There is also the inevitable exhibition. But, again, the accent is not upon inquiry into those remedies which appear to have some pharmacological activity, it is not upon making a critical effort to harvest what is good and reject what is useless, it is upon presenting and sustaining and increasing the influence of the whole tradition as it is and has for ages been.

---

[1] Fox T F *Lancet* 1957, ii 935
[2] Fu Lien-Chang *Chin. med J* 1955, 73, 363 This article also appeared at the front of eight other professional journals

It is hard to imagine how the methods of science could usefully be applied to acupuncture, but in the field of herbal medicine there is obvious ground for fruitful research Chen and Schmidt's work on ephedrine is the classical example of what may be achieved It is therefore disappointing to find that such work is not a major effort within the central temple of herbal medicine, and to be told, in answer to a question, that " Chemical analysis is also undertaken, but is not the main aim of research, because from some of the herbs it is not possible to extract the active principle " The belief is encouraged that the art is being boosted for purposes other than its possible contribution to a system of rational therapy

True enough, work of the Chen-Schmidt type is going on in China, but such efforts are largely made not at the centres of herbal medicine but in the medical schools and hospitals where Western doctors are being so vigorously urged to " cooperate " and show a lively interest in their traditional heritage

THE FUTURE

My host at the Institute of Herbal Medicine told me of future plans

Doctors will get their training in Chinese medicine whilst undergraduates in the medical schools No new purely traditional doctors will be produced The modern and the traditional modes will be taught side by side, so that after a period there will no longer be two groups of doctors in China, but a single group composed of men trained in the new synthetic lore There will not be texts on traditional medicine and other texts on Western medicine, but new books will be written to combine the teachings of the two disciplines There will not be teachers of the old and others to teach the new, instead each teacher will preach the double gospel, not as separate subjects, but as one This is for herbal medicine Acupuncture, which is a " specialty ", will have its own share of the curriculum, amounting to some 160 hours

However, the full synthetic course will not operate until after the end of the third Five Year Plan, and that time lies ten years from now

A more recent assessment of the situation was given last year by Ho Piao[3], vice-minister at the Ministry of Health Reviewing the development of hygiene and health work under the first Five Year Plan, he wrote

> " During the past few years great efforts have been made in developing traditional medicine In China there are now more than 500,000 traditional practitioners with over 40,000 apprentices Four colleges for the teaching of traditional Chinese medicine have been opened together with six schools and twenty-three centres for refresher courses In addition there are 144 hospitals and 453 clinics where traditional Chinese medicine is practised exclusively Over 20,000 traditional doctors have joined the government health service At present 5,000 highly trained modern doctors are studying traditional medicine, among whom 300 are devoting their full time to it An institute for research into traditional medicine has been established All colleges of medicine and pharmacy pay particular attention to research into traditional Chinese medicine and pharmacy "

This statement hardly suggests that the pure herbalist is on the way out, on the contrary it shows that earlier plans for boosting traditional medicine are being vigorously pursued So far as " cooperation " between the old and the new is concerned, the picture seems wholly one-sided " 5,000 modern doctors are studying traditional medicine " (despite the crying need for their efforts in other tasks) There is no mention of traditional doctors being trained in Western ideas

A marriage having been ordained, one unwilling partner is being steadily forced by determined in-laws toward an unhappy consummation How will the children turn out ?

INCOMPATIBLES

There is no strict proof that the ultimate will of God is expressed in the being of the Royal College of Physicians of London (however some of the Fellows may feel), and, on the other side, there is no doubt that the herbal doctor in China provides, and has for centuries provided, services sorely needed by a sick man and his relatives The choice between modern and traditional medicine is not, therefore, a choice between the ideally good and the wholly bad Nevertheless an equally absolute difference does divide the two One is science and the other is not

Herbal medicine is a mixture of empiricism and superstition acupuncture is unspoiled magic The whole nature of contemporary Western medical thought and practice rests upon the rules of science It is therefore logically impossible to teach the two systems effectively side by side, for a man who believes in the one cannot appreciate the other It must follow that a man cannot teach or learn or practise both together unless he avoids thinking about either

The whole medical effort must be reduced to the faithful practice of decrees Doctors must recognise the Party as the only competent authority in medicine, as in all else And first among the results to be expected is that advance will cease *Medicine in China must look forward to* a period of inanition exactly parallel to that which seized medicine in Europe for centuries under the grip of the galenical philosophy The only advances permitted will be those introduced from outside after careful vetting and approval by the State

Is this what is required and foreseen ?

AN EXPLANATION

I have two reasons for suggesting that the Chinese Government does want and expect the results I have imagined Firstly it is an accepted working rule of historians that an intelligent man foresees the logical consequences of his deeds, and there is certainly no doubt that the present leaders of China are highly intelligent Secondly, it is significant that the full synthetic training is not to be introduced for another ten years Mao Tse-Tung pronounced the need for cooperation between modern and traditional doctors in October, 1944 Admittedly, the training of teachers and the writing of texts must precede remodelling of the medical course, but by Communist standards, twenty-four years is a strangely long preparatory period, and out of keeping with what we know of their usual rate of progress towards a decided end However, if the leaders realise how their programme must alter the whole nature of medical thought and practice in China, then another reason for delay emerges

The present structure of medical services and medical training must depend largely upon the work and enthusiasm of doctors and medical scientists who have had their training in Western schools, either inside or outside China, many of the best of whom will have spent some time abroad in postgraduate training and practice It is essential to retain the effective services of these men until they can be replaced by more amenable domestic products It would be impossible to bring about their genuine conversion to the ancient faiths The Government is showing its wisdom in not risking shipwreck by forcing too sharp a change of course

Then, if the consequences are foreseen, what is the motive ? It is certainly nothing trivial like a misguided chauvinism, or an undue influence by vested interests in high places The effort is far too large, the results too grave, to allow belief in such answers Is the movement inspired by a deep governmental faith in the "scientific" virtues of traditional medicine? That would be a curious judgment from a group of hardheaded dialectical materialists Is it simply an attempt to make the native cures seem good to the people in view of the fact that for many years to come no other sort of medical care will be available to most of China's millions? This would be a satisfying answer if the main effort was in public propaganda supporting herbalism It is no explanation for the changes being forced upon Western practice

---

[3] Ho Piao *ibid* 75, 953

Possibly there is no one answer, and possibly some or all of the factors just considered helped to shape policy, but I suggest that a prime and purely political motive lies behind all

The doctor, unlike the chemist or the physicist or the engineer, is necessarily always in close contact with the people of the community he serves, and if he is any good at all he has a large, personal, and direct influence on his patients and on his patients' friends and relations I suggest that a man trained in the critical and almost iconoclastic school of contemporary Western medicine is not a suitable person to wield moral and intellectual authority among the citizens of a Communist State If he himself is a dedicated believer in Marx-Leninism, he may achieve a sort of working schizophrenia, having a mystical faith in the gods of State, whilst keeping a fairly effective spirit of independence and inquiry alive within the half of his mind that he uses for his job When conflict occurs, as sometimes it will, the mystical half of the mind will prevail, and the professional half will suffer a few blind spots —but probably not too many or too large to cripple him as a scientific doctor

However, most citizens in a Communist State are not dedicated Communists (any more than most citizens in a democracy are dedicated Democrats or Conservatives), and it is the educated but undedicated who is most likely to become the revisionist, the dangerous liberal, the traitorous reactionary

I suggest that the Government of the People's Republic of China realises full well that it cannot risk educating tens of thousands of young men and women into the habits of critical thought regarding people, and self-reliance in handling people, that a man must have for the successful practice and understanding of modern Western medicine Even less can the State afford to let such hordes of dangerous thinkers loose among the masses I believe that the forcible dilution of Western medicine with old magic is an attempt to produce a new species of medical animal, still capable of acting in a priestly role as comforter of the sick, still capable of practising modern and indispensable techniques according to the book, but without that perilous turn of mind that kicks against the pricks and asks a sound argument for every thesis

APOLOGIA

To Western and non-Communist minds this explanation may appear impossibly far-fetched. The danger to the State that I have conjured up is so nebulous, the remedy so heroic But the curious happenings are there and must be explained Consideration of two relevant circumstances may make my interpretation seem less fanciful

To a true Communist there is only one, supreme, inviolable science, and that is the science of Communism All other facts, disciplines, and behaviours must fit the sacred doctrine, or change to fit, or be abolished What to an unpolitical scientist seems grossest cynicism or illogic, may to a Communist appear as common sense In the Communist vocabulary, expediency is a synonym of truth. I stress this not as political criticism (which is not the purpose of my writing) but to make the point that the assault on medical science taking place in China today is not necessarily inspired by motives that would make good sense to a non-Communist mind Indeed, to the Communist mind, the happenings here described may not appear as an assault at all

The second circumstance is peculiar to China Before the Communist revolution the better medical schools were largely run by foreigners The outstandingly excellent Peking Union Medical College was owned by the China Medical Board, endowed from Rockefeller funds Many of the others of good standing were owned by missionary societies

For years the Chinese had resented foreign management of their affairs, and I have the impression that missionaries were resented more than most, despite their simple wish to serve Because of this foreign hold on medical education and services, the profession in China had closer links with the unpopular West than any other important native group When the Communists drove south and took the land, they must have looked with particular suspicion upon the doctors who had been nurtured by American gold and Caucasian Christians

One last implication The new Chinese medicine can flourish only if its practitioners are kept effectively isolated from Western thought It is difficult to see how isolation can be long maintained whilst both outlooks survive Possibly the active promotion of the one betrays an assumption that the other faces short shrift

ANTIVACCINIAL GAMMA-GLOBULIN IN SMALLPOX PROPHYLAXIS

E R PEIRCE
M R C S , D P H , D T M
LATELY MEDICAL OFFICER IN CHARGE OF NEW FERRY ISOLATION HOSPITAL

F S MELVILLE
M B Edin , D P H
MEDICAL OFFICER OF HEALTH, BEBINGTON

A W DOWNIE
M D Aberd , F R S
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LIVERPOOL

MARJORIE J DUCKWORTH
M B Lpool
ASSISTANT LECTURER IN BACTERIOLOGY IN THE UNIVERSITY

GAMMA-GLOBULIN prepared from adult serum has been used successfully in measles prophylaxis for some years, and since 1956 gamma-globulin, prepared from the serum of recently vaccinated or revaccinated adults, has been available, through the Public Health Laboratory Service, for smallpox contacts As yet, however, there is little evidence as to the efficacy of this antivaccinial immune globulin

Field trials were reported by Kempe, Berge, and England in 1956 In Madras, in 1953, 56 household contacts of smallpox cases were vaccinated and given vaccinia immune gamma-globulin, while a control group of 75 household contacts were vaccinated only Of the first group 2 subsequently developed smallpox and 1 died, while in the control group there were 8 cases of smallpox with 3 deaths In the same report evidence is presented of the value of gamma-globulin in the prevention of generalised vaccinial infection in eczematous children who required vaccination or who were exposed to recently vaccinated children

In the Tottenham outbreak of smallpox last year vaccination was supplemented by vaccinia immune gamma-globulin for primary contacts who had not been previously vaccinated

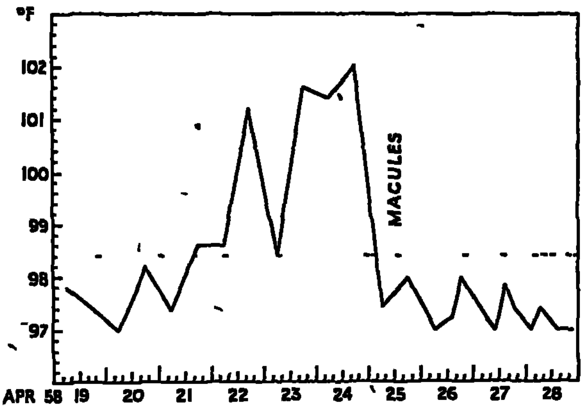

Fig 1—Temperature chart of case 3, J L, aged 6

(Hogben, McKendrick, and Nicol 1958) None of these developed smallpox

The recent occurrence of smallpox on Merseyside provided an opportunity to observe the effect of gamma-globulin, prepared from the serum of recently vaccinated individuals, on close family contacts of the second case

History of the Outbreak

THE FIRST CASE

The *Circassia* arrived at Liverpool on the evening of March 19, having on board a coloured seaman with smallpox He had become ill on March 9, eleven days after leaving Bombay, and the rash had appeared on March 12 On arrival he had a severe confluent pustular eruption He was landed by the fireboat *William Gregson* and taken by ambulance to the Smallpox Hospital, New Ferry By March 24 the lesions were drying up

At the Smallpox Hospital the usual precautions were taken about disposal of scabs, disinfection of floors and disposal of bed linen After the patient's admission no-one entered or left the hospital grounds except medical personnel and the matron of the parent hospital Stores were sent from the parent hospital, milk and groceries were left outside the main gates

THE SECOND CASE

Family L lived in a row of houses about 400 yards from the Smallpox Hospital

The son, T L, aged 1 year and 11 months, unvaccinated, had been confined to his home for a fortnight before March 21, because of mumps On March 25 he was taken by his mother to the hairdresser's On April 6 he appeared to be suffering from a heavy cold and was generally " out of sorts " On April 9 a rash appeared on his face, and next day it had spread to his arms and legs On April 14, at his doctor's request, he was seen by two of us (F S M and E R P), a diagnosis of severe discrete smallpox was made and he was admitted to the Smallpox Hospital The eruption was pustular, semiconfluent on the face, and profuse on the extremities He was extremely ill From admission he was given one million units of penicillin daily On April 18 his condition was still very poor, and 2 5 mg of cortisone in orange juice was given twice daily by mouth for three days On April 20, when the lesions were beginning to dry up, he showed definite improvement, and with the fall in temperature next day cortisone and penicillin were stopped By May 8 most of the crusts had separated, though a few remained on the scalp He was discharged from hospital on May 17

T L had been at home during the first six days of the eruptive stage of his illness and his family contacts had been heavily exposed They were his father, Mr L, aged 37, vaccinated in infancy and during war service, his mother, Mrs L, 40, vaccinated in infancy and again successfully in 1946, his sister, J L, 6, unvaccinated, and his grandmother, Mrs K, 73, vaccinated in infancy These family contacts were vaccinated on April 14 and kept in isolation at home (Other known contacts of T L were vaccinated between April 14 and 16) But J L and Mrs K had been heavily exposed to infection for so long that vaccination seemed unlikely to protect them Immune gamma-globulin was sent by Dr J C McDonald of the Central Public Health Laboratory, Colindale, London, and on April 15 1 5 g dissolved in 12 5 ml distilled water was injected intramuscularly into J L, and 1 0 g similarly given to Mrs K On April 16 a further 0 5 g was given to J L

Reactions to vaccination—Mr and Mrs L both had accelerated reactions maximal about the fourth day Mrs K had the reaction characteristic of primary vaccination, with axillary adenitis, and after nine days the large vesicular take still showed no sign of drying The reaction of J L was also primary in type but without adenitis At eight days she had a small vesicle surrounded by a well-marked areola, but next day this was much less and a central scab had formed—rather earlier than might be expected in a typical primary take

THE THIRD CASE

On April 21, seven days after vaccination and twelve days after the appearance of the focal eruption in her brother, J L had a slight evening rise of temperature

Her temperature chart is shown in fig 1 During these days when the temperature was raised she had no headache, backache, or sore throat, she felt quite well and played at home during the day On April 25, when her temperature had returned to normal, two small red papules were present on her right forearm, one on her forehead, and one macular lesion on the back of her right hand and one on her left thigh Scrapings from the lesion on the back of her hand showed no virus on direct microscopical examination but produced typical variola lesions on the chorioallantois of chick embryos Next day a few more lesions were seen fig 2 shows the position of all the lesions on April 28 From lesions scraped on April 26 and 27 smallpox virus was recovered on inoculated chick embryos The patient had been removed to the Smallpox Hospital on April 26, but she had no further rise of temperature The lesions never developed into typical smallpox pustules, some developed tiny vesicles before drying up and others never progressed beyond the papular stage

Had she not been under daily supervision this child would not have been recognised as a case of smallpox

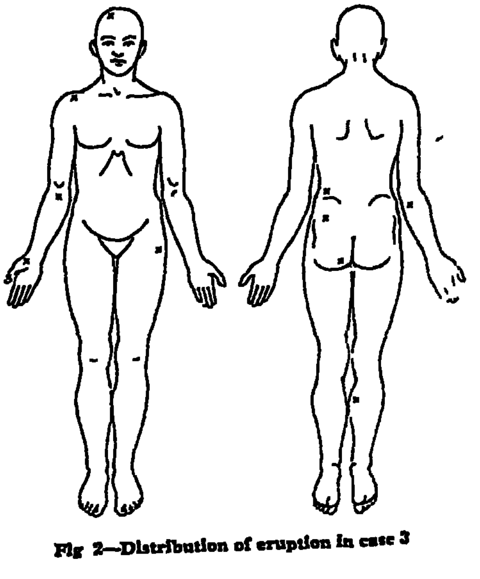

Fig 2—Distribution of eruption in case 3

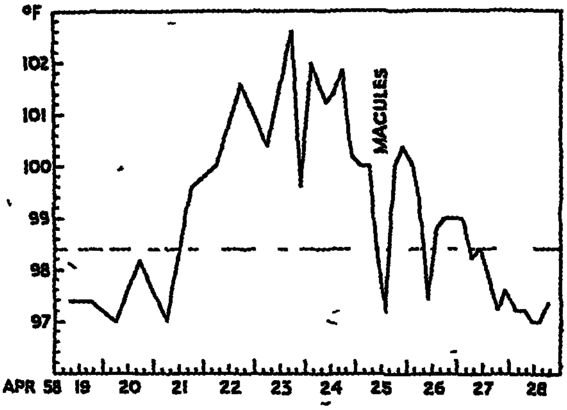

Fig 3—Temperature chart of case 4, Mrs K., aged 73

THE FOURTH CASE

Mrs K., the grandmother, also had a slight rise of temperature in the evening of April 21

Next day her temperature was higher and she complained of axillary adenitis apparently due to her vaccination which was vesicular at this time Her temperature chart is shown in fig 3 On April 23 she had a profuse discrete macular rash and was admitted to the Smallpox Hospital Next day the rash was generalised like that of a severe rubella It was absent from the face, sparse on the hands and feet, but profuse on arms, back, chest, abdomen, and thighs, and confluent over the scapular and lower lumbar region This was probably a prodromal rash Scrapings taken from the eruption on the left forearm failed to show virus by inoculation of chick embryos

On April 25 her temperature was normal and the generalised rash was fading She had a few maculopapular lesions, however—one on each thigh, one on left forearm, and one on the right thumb Scrapings from this last lesion showed virus particles on direct microscopical examination and produced typical variola lesions on the chick chorioallantois On April 28 focal lesions, rather atypical in distribution, were present as shown in fig 4 From lesions examined on the 26th and 27th virus was recovered by chick-embryo inoculation Some of the lesions had become pustular by the 27th and 28th but they dried up thereafter

Although this patient had rather more general disturbance than J L (case 3), and had an extensive prodromal rash, there was no secondary fever and the illness ran a mild course

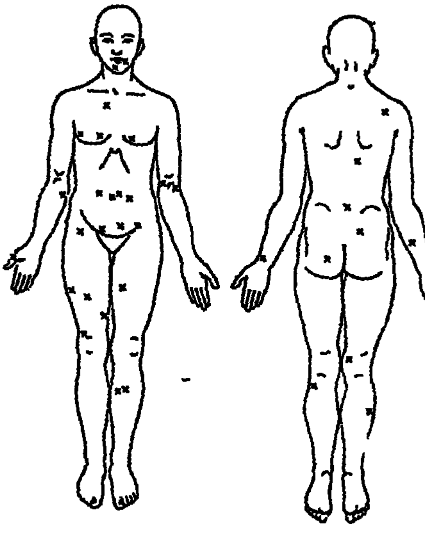

Fig 4—Distribution of eruption in case 4

Garglings

Garglings usually contain virus from about the time that the focal rash appears (MacCallum, McPherson, and Johnstone 1950, Downie and McCarthy 1954)

Garglings had been collected from cases 3 and 4 daily from April 18 to 29th inclusive—i e, from three days before the onset of fever until eight days thereafter They had been kept at −70°C until examined on May 1, 6, and 9 Specimens were spun at 10,000 r p m for thirty minutes, and the deposit (suspended in fluid containing streptomycin and penicillin) was tested for virus by inoculation on the chorioallantois of chick embryos From none of the specimens was virus recovered even by two or three passes of the inoculated membranes to further chick embryos That virus had not disappeared from the specimens during storage was suggested by examination of garglings from case 6 A specimen taken from this patient on the seventh day of illness was heavily infected with virus, and the titre had not diminished after a month's storage of a portion of the specimen at −70°C

Neither case 3 nor case 4 ever showed any obvious lesions in the mouth, and the failure to find virus in garglings suggests that their throat and mouth secretions were not highly infective

THE FIFTH AND SIXTH CASES

As contacts of case 2 had been kept under surveillance until May 1 and no further case had been reported up to May 10, the outbreak was thought to be at an end However, a man, Mr G, aged 54 (case 6) was admitted to Clatterbridge Hospital as a case of meningitis on May 17 He had a hæmorrhagic rash and was extremely toxic He was seen by two of us (F S M and E R P) several hours after admission and recognised as a case of hæmorrhagic smallpox

He was removed to the Smallpox Hospital where he died three days later Material from his skin lesions showed virus on laboratory examination As his wife was known to have been a contact of case 2, this man, who had been vaccinated in infancy only, had been revaccinated on April 16 This vaccination produced no take and he was told by the health visitor, who called daily, that he should report to the clinic to have the vaccination repeated, but he did not see fit to do so His illness began on May 12, but he went to work this day and the next He visited his doctor on May 17 and from there was sent to hospital

His contacts, including those at the doctor's surgery and at the general hospital, were vaccinated, and 9, who had not previously been vaccinated, were given immune gamma-globulin None of these contacts developed smallpox

As the wife of case 6 had visited the home of case 2 just before case 2 was admitted to hospital on April 14, she was examined immediately after the nature of her husband's illness was recognised

On May 18 there appeared to be a few old crusting lesions From three of these, one in the palm of the hand and two on the trunk, crusts were removed and extracted together for inoculation of chick embryos Smallpox virus was recovered This woman (case 5) had been vaccinated in infancy and again on April 15, one day after contact with case 2 This last vaccination gave a good slightly accelerated primary take which left two good scars She had been visited daily by a health visitor until May 1, but no illness had been recorded. On May 1, 2, and 3 she had an influenza-like illness This illness occurred seventeen days after her last possible contact with case 2 and eleven days before her husband sickened

If this woman's illness on May 1–3 was mild smallpox, the incubation period was longer than that usually accepted (ten to fourteen days) and the incubation period of her husband (case 6) rather less than the average

Discussion

This outbreak was one of variola major originating in India The first 2 cases were extremely severe, with semiconfluent eruptions, while the 6th case died of a hæmorrhagic form of the disease It is difficult to assess the prophylactic value of gamma-globulin given to contacts of cases, because of the uncertainty of infection being acquired by such contacts

Only planned experiments such as that of Kempe et al in India can quickly provide conclusive evidence Nevertheless, the observations on cases 3 and 4 suggest that immune gamma-globulin greatly ameliorates the course of smallpox after infection has been acquired These 2 patients, one unvaccinated and one vaccinated over seventy years previously, had been for several days in contact with case 2 before the diagnosis of smallpox was made If one allows for an incubation period of twelve days in cases 3 and 4—although this may have been prolonged by the administration of gamma-globulin—vaccination was not carried out until the fifth day after their infection Primary vaccination at this stage in the incubation period is believed to have little protective value While the immunity response after revaccination may be fairly rapid (McCarthy, Downie, and Bradley 1958) the primary type of take shown by Mrs K indicated that she had little or no residual immunity from her childhood vaccination We believe that the extremely mild course of infection in case 3 and the mild smallpox in case 4 can be attributed to the gamma-globulin given to these patients seven days before their illness, and not to their successful vaccination The absence of virus from their garglings is not altogether surprising since neither patient had detectable lesions in the mouth or pharynx

The dose of gamma-globulin given to case 3 (aged 6) was 2 grammes—twice the dose recommended for adult contacts This represents several hundred millilitres of vaccinia convalescent serum The gamma-globulin used was tested for variola-neutralising antibody by the chorioallantoic membrane technique (McCarthy and Downie 1953) A 1% solution gave more than 50% neutralisation of variola virus in fivefold dilution up to and including the dilution of 1 in 125

Mrs G (case 5) also had a mild infection, but the mildness of her disease can probably be attributed to vaccination in infancy followed by successful revaccination the day after her contact with case 2

Summary

The outbreak of smallpox in Merseyside comprised 6 cases, the first being an Asiatic seaman infected in Bombay

The 2nd case was a boy about 2 years old who remained at home for the first nine days of his illness

In close contact with him were his sister aged 6 (case 3) who had never been vaccinated and his grandmother aged 73 (case 4), vaccinated in infancy

These were vaccinated seven days before the onset of their clinical infection, but probably this had little effect The mildness of their illness is attributed to immune gamma-globulin given on the day after their vaccination

THAT DAMNED WORD HEALTH

I GORDON
M D Edin , M R C P , D P H
MEDICAL OFFICER OF HEALTH, ILFORD

> "Health is a state of complete physical, mental, and social wellbeing, and not merely the absence of disease or infirmity "—
> WORLD HEALTH ORGANISATION

IN considering health we must remember that the problem is biological—not theological, as might almost be assumed from the above definition,[1] or political, as might be supposed from the origins and course of the National Health Service

Man, like other organisms, is evolving continuously, for better or worse, within his environment, and when a person's contact with his environment, internal or external, is deleterious, he is bound to suffer some damage, though this may not be permanent or even appreciable He makes an effort to overcome any disability thus caused, and numberless times during his lifetime each individual moves from apparent defeat to apparent victory An apparent defeat may cause the effort leading to apparent victory, and an apparent victory the lack of effort leading to apparent or real defeat For defeat read illness, for victory, health

To maintain his equilibrium with his environment, man and his species are in perpetual struggle—with microbes, with incompatible mothers-in-law, with drunken car-drivers, and with cosmic rays from Outer Space How then, in this context of movement and buffeting back and forth between organism and environment, can we find any place for the woolly-headed definitions of " positive health ", as a state that can and must be considered apart from disease? It is as if we were to insist on discussing white without mentioning black, hot, without intruding with that dreadful word cold In the living there is no such thing as complete health, any more than there is complete disease (which is death) each organism is somewhere between the two, as each temperature is somewhere between absolute minimum and absolute maximum We all of us have something of disease with us, even if it is only an acne spot today and food-poisoning tomorrow Disease began to corrode us the moment we were conceived, if not before In fact, we may be higher up the ladder of health by virtue of some imperfection, as the life-history of many a handicapped person, has shown, it may be healthy to have something wrong

People who talk about positive health have become confused The " positiveness " of health does not lie in the state, but in the struggle—the effort to reach a goal which in its perfection is unattainable

* * *

This attempt to separate health from disease is of more than academic importance it has had devastating effects on the structure of the National Health Service and other statutory services The local health authorities generally deal with those who are presumed to be well, and the hospitals with the sick, so in the same convalescent home one may find two men, one of whom is sent for recuperation by the local authority and has to pay or be assessed, while the other is sent for convalescence by the hospital and does not have to pay a penny, though he may not be any more ill Even in the one service, district nursing is free and domestic help for the same sick person is not The worst example of the outcome of this false philosophy is that local-authority welfare activities for the aged are separated from medicine Whether a person is "aged and infirm" or "aged and sick" is often a matter of doubt, and may vary from day to day, it is something on which doctor may differ from doctor, or doctor from welfare officer Yet on the opinion which prevails the old person may receive accommodation or be denied it—may be made to pay or freed from monetary worries Even the expectant mother bears a smaller financial burden if she enters a maternity hospital than if she is confined at home

---

[1] See also A Study in the Epidemiology of Health , published by the Kent Pædiatric Society from 11, Brampton Road, Bexleyheath Kent.

When the B B C produced its programme "Your Life in Their Hands," the *British Medical Journal*[2] accused it of concentrating on "disease education" It suggested that disease should not be discussed on television, where the emphasis should be on health But of course it is quite impossible to discuss health with intelligent people without simultaneously discussing disease Are we to tell the inquiring student of health not to smoke without describing bronchitis or cancer of the lung, or what to eat without telling him about scurvy, rickets, or beriberi? The *British Medical Journal* points out that the operative word in the National Health Service is *Health*, as if this somehow disguises the fact that fundamentally it is a bed-and-bottle service Even the World Health Organisation, in spite of its name and its erroneous definition of health, concerns itself (and quite rightly) mainly with disease, as does the Ministry of Health

Medical officers of health themselves are not always clear about the impossibility of separating health from disease. They, and the Ministry of Education, tend to evaluate school medical inspections by the number and accuracy of the defects noted if none are noted, either the examining doctor didn't do his job properly or the child was perfect It is not so, all children have defects, and the fundamental job of the school medical officer at a routine examination is to decide which are significant and to inform the parents accordingly. The lists of defects that obsess clerical staffs and the Ministry are but a minor, inaccurate, and variable excretion of a very important (even though hurried and harassed) medical examination Inasmuch as this evaluation of the indefinite borderline between health and disease concerns every child, such work is even more important than the highly specialised technique of advising the obviously handicapped

My colleagues in public health have tended to adopt the fashionable view that "health" is a more noble term than "medicine" because the latter implies contact with disease Hence the imaginary elevation of the School Medical Service to the School Health Service However, they are now coming to regret this, for Health does not pay as well as Medicine (i e, disease), nor are its exponents as well respected. The sooner the Society of Medical Officers of Health insists on using the terms "community medicine" or "community physician" in its title, and drops the word "health", the earlier will it command the attention it deserves in the nation's counsels Let the word health be the prerogative of the Royal Society of Health and the Public Health Inspectorate, and others whose training and function are not intimately connected with disease

* * *

When there is discussion of "positive health"—a state to be considered apart from disease—in the words of the late but unlamented German field marshal, "I reach for my gun"

In England Now

A Running Commentary by Peripatetic Correspondents

Charles was always a bit of a devil for making a clean sweep Perhaps some radical streak in his nature led him to take up surgery Perhaps the disciples of that art are inclined to favour total extirpation of any pretty frills that stand in the way of stark function It all seemed rather heroic from my end of the table I used to give dopes for Charles in the old rag-and-bottle days, and I remember watching him open up an abdomen that had defied the diagnostic skill of physician and surgeon alike In went his hand for the lucky dip, out popped a rather seedy looking appendix Charles eyed it with distaste. Its obvious chronicity offended his dignity by all rights it should have burst during the attack before last, but it did not it lay there across his finger and sneered back Charles performed his usual pretty appendicectomy as a side-line to a dissertation on downdraught carburettors, and pushed the rest back He rummaged about in the pelvis and his eyes lit up With some difficulty a fibroid uterus was coaxed out under the floodlights, and we were treated to a gynæcological exhibition turn for the next twenty minutes After the hysterectomy I was getting ready to doze off myself with the warmth and the ether fumes, when Charles complained profanely that the patient was not relaxed enough for him to get on with the original aim of an exploratory laparotomy I sighed and Mrs Ugglethorpe sank deeper into oblivion Her gallbladder was rattling like a dice-box with stones, so she lost that little lot. There was rather a hollow echo as her abdominal wall was stitched. She could never complain that she had not had her money's worth Actually she did very well afterwards, but that is beside the point

Charles lives about thirty miles outside Town, and has the sort of garden that consultants are expected to have He also has no gardener Twin carburettors and an elegant suite of rooms in Wimpole Street are completely neutralised if appearances are not kept up at Riverside Lodge The grass was too long and tough for a mower Charles did not think that his lumbar discs would endure sufficient torsion for the good old-fashioned scythe Mary refused downright to get on her knees with the shears, and managed to persuade him to hire the mechanical scythe from the golf club On Sunday afternoon he started it up and trundled the thing chattering towards the lawn. It made a grand job right across the mid-line We waited for Charles to swing it round the other way he was red in the face and running by then the engine was roaring, so was Charles Straight over the rose beds they went Fanny Blankers-Koen was overtaken, Mrs Sam McGredy was cut off in her prime, General MacArthur fell to the sword, Anne-Else and Karen Poulsen were guillotined in one unhappy family group On through the borders in front of the house Azaleas, red hot pokers, carnations, and delphiniums fell in piles So did *Hamamelis mollis* I had visions of Mary being trapped against the wall and serially sectioned by the runaway microtome, but, with a last despairing wail, Charles tugged at the offside handlebar and then let go The aid to surgery fell into the river

I was most unpopular for mentioning Mrs Ugglethorpe.

* * *

Malaria is not a disease which one expects to see every day, or indeed every other day, north of Hadrian's Wall I was slightly taken aback, therefore, to be summoned by my Chief to see a case of malaria late one evening

By the time I arrived he had departed and I was left with the problem But the blood-film confirmed the diagnosis, and only the knowledge that the Chief had been a classical scholar in his youth prevented me from sending him a telegram Veni, Vidi, Vivax!

* * *

Mrs. McLaren, despite her name, was French She was in her 76th year, immensely entertaining, and remarkably vivacious for a woman of her age. Unfortunately her gallbladder was full of stones and she had been admitted because of recurring attacks of severe biliary colic Operation was advised and was firmly refused for no very definite reason I resolved to make a final persuasive effort but she shook her head and said, " I am very stubborn, my mother used to say I was the most stubborn woman in Paris "

---

[2] Brit med J 1958, i, 510

Then I remembered the charming Oscar Wilde story of the lady who prided herself on her lack of beauty Bravely embarking on my patient's native tongue I began the tale " Dites-moi, Monsieur, si je ne suis pas la femme la plus laide a Paris ?" " Mais, Madame, dans tout le monde!" Wilde, the kindest of men, recorded that the lady was delighted So was Mrs McLaren Almost embracing me, she cried, " Très bien, Monsieur le Docteur, tres bien My gallbladder, it is yours "

* * *

For the annual general meeting our society usually manages to muster some 5% of its membership, consisting of the executive committee plus a few rash youths who lack enough intelligence to understand that regular attendance at annual meetings (i e , attendance at two consecutive meetings) carries a grave risk of nomination and unanimous election to the executive Myself, I was very shabbily treated As a newcomer I attended two A G M 's, but when I skipped the third I was nominated and elected to the executive *in absentia* The first I heard of this was 10 months later, when I was summoned to the next meeting of the executive Sense of responsibility made me attend subsequent meetings, until after about 7 years I realised that all of the older members had " been through the chair " While I was vice-chairman, I was reprieved when it was suggested that the chairman should hold office for a further year This had happened only once before , but I was prepared to ignore the apparent insult, in return for not having to officiate at our first annual dance

You see, I last went to a dance shortly before the war In those days I was courting hard, and affected a personal version of the soft-shoe-shuffle But 19 years is a long time, something had to be done despite the year of grace After 11 months of procrastination, and an urgent phone call to a local dancing academy, I attended a " private lesson " session Everyone was very kind to me One lesson taught me the rudiments of a slow waltz, and one the basis of a quickstep Each night I lay awake, twitching, one, two, together or slow, slow, quick-quick slow

When the great day came, of course there were so many people there that, whatever their abilities, there was no room to do more than the old soft-shoe-shuffle (What is the use of learning to dance if on the floor one cannot go ahead on a north-north-westerly bearing for another two yards, without hazarding the ship and sinking with all hands on each leg of the course ?) By 11 P M I was ready for bed by 1 A M I was out on my feet, the only sign or symptom of continuing consciousness being a splitting headache At 2 A M I was allowed out to relieve the baby-sitter My halo lay heavily on me when I found that everybody seemed to think that I had enjoyed the proceedings as much as they had

I really must get on with these dancing lessons in good time this year The duties of chairman at such a function are hardly onerous enough to excuse him from taking the floor at all

* * *

Perhaps it was subconscious confusion which led a pupil midwife in answering a question about the virtues of breast-feeding to write, " The breast-fed baby is more contented as it lies curdled in its mother's arms "

* * *

Junior Partner I thought you said you believe in telling the patient the truth

Senior Partner So I do

J P Then why did you tell Mrs *P* that she had a strong heart ? In fact you said she has an " exceptionally strong heart "

S P So she has

J P How can she, when she's had coronary thrombosis twice and has a blood-pressure at least double your own ?

S P My boy, any heart which can support a blood-pressure of those dimensions after two thromboses must be exceptionally strong!

Letters to the Editor

UBIQUITOUS STAPHYLOCOCCUS

SIR,—We are all, now, familiar with the ubiquity of the staphylococcus in the hospital air and dust and with its deadly characters So much has in fact been written and so intense has been the attack on typing and categorising the organism that we are rapidly losing sight of the most urgent need—a return to the practice of aseptic method

I have recently made post-mortem examinations on patients who, having survived postoperative pulmonary embolism, have died with staphylococcal abscesses within the pulmonary infarcts In some of the cases there had been a staphylococcal wound infection in the immediate postoperative period

Bacteriological examination of necropsy material, so often neglected, continues to provide a sinister reminder of the omnipresence of the staphylococcus and points clearly to the remedy—aseptic method

This remedy will prove expensive in staff and materials Nevertheless it must be applied sooner or later We are asking too much of the human body and its powers of resistance to injury when we add to deadly pulmonary embolism the mortal blow of staphylococcal toxæmia

Department of Pathology,
University of Cambridge G A GRESHAM

IMPORTANCE OF INTRAVENOUS INJECTION OF DIPHTHERIA ANTISERUM

SIR,—I read the article by Dr Tasman and his colleagues [1] with considerable interest They suggest that the intravenous injection of antiserum in patients suspected of having diphtheria ought to replace the still common practice of giving it intramuscularly, for the following reasons

(1) 100% of the highest antitoxin titre is obtained *the first* day after the injection

(2) The saliva contains antitoxin after only 30 min

(3) The advantages of intravenous injection were clearly illustrated by the protection of guineapigs injected with lethal doses of diphtheria toxin

I think, however, that their process of reasoning is not altogether free from criticism

(1) The intravenous injection of a certain amount of antiserum gives 100% of the highest titre (how many antitoxin units in the blood ?), when given intramuscularly only 50% (table II, p 1299) If, however, we inject intramuscularly twice as much antiserum, or more, the antitoxin titres the first day after the injection may be the same

(2) The early or late excretion of antitoxin in the saliva is not a significant phenomenon, if antitoxin titres in the blood are adequate they neutralise the absorption of the toxin with the saliva

(3) The experiments on guineapigs cannot be transferred to man the moment of infection is not known, and in the experiments with guineapigs the same doses of antitoxin have been used in intramuscular and in intravenous injections Another experiment, giving the guineapigs twice as much antitoxin intramuscularly, might be profitable

On the question of anaphylaxis, I do not think any test gives 100% guarantee of safety Although in my clinic we use a well-purified antiserum only intramuscularly, never omitting the skin test, and although we inject the antiserum in small doses at intervals, we have had a few rare instances of serious allergic reactions

The amount of antiserum injected for diphtheria varies considerably in different countries and is often based on tradition, or on more or less statistically evaluated results of treatment, but we have no exact theoretical means of estimating the amount of antitoxin really needed.

J. BOGDANOWICZ

TREATMENT OF BREAST CANCER

SIR,—The declared object of radical mastectomy as well as of limited mastectomy plus subsequent radiotherapy is to eradicate all tumour tissue from the chest wall and from the axilla.

Success or failure may or may not be reflected in the five-year-survival rate, which is influenced by such other features as clinical stage and histological character of the tumour. The effectiveness of these treatments could, however, be expressed by stating the proportion of patients who (*a*) remain free of any clinical manifestation of the disease on the chest wall or in the axilla for five consecutive years after the first intervention, (*b*) die within five years without such manifestation (of metastases), (*c*) survive for five years but show disease on the chest wall or in the axilla; (*d*) die within five years with, but not necessarily of, disease on the chest wall or in the axilla.

These results should be stated for each of the various stages according to a simple (Steinthal) classification. Such information from those who are in a position to analyse a large number of cases would present a more rational basis for advice on appropriate treatment than many of the statistics which have little clinical significance.

CHLORPROPAMIDE

SIR,—I am interested in the account of the trials of chlorpropamide reported by Dr. Murray and his colleagues in your issue of Sept. 13. Unfortunately my experience in treating a similar group of 43 diabetics has not been correspondingly satisfactory, nor yet as good as mine with the generally abandoned carbutamide.[1]

The investigation began in February, 1958. 43 diabetics had chlorpromazine, but only 3 were under observation as inpatients. There were 11 men and 32 women. The choice of case and the conditions under which they were treated were no different from those under the now familiar tolbutamide therapy. Only 3 patients were under 50 years of age. 23 patients had been diabetic for less than two years and 20 for longer, up to 23 years; previous treatment had been by insulin in 21, tolbutamide in 3, and diet alone in 19.

Dosage.—In the earlier cases 0.5 g. of chlorpropamide was given three times a day after food, with a smaller maintenance dose. As our experience increased, the initial dose was reduced and the later cases in the series received only 0.5 g. or 0.2 g. daily in a single dose after breakfast. A fall in blood-sugar to below 200 mg. per 100 ml. occurred in 38 cases and was maintained at a satisfactory level. Actual hypoglycæmic symptoms were recognised in 1 case only. In 6 patients there was inadequate or no hypoglycæmic effect, and in 1 man who appeared to be doing well an intercurrent bladder infection associated with a carcinoma necessitated a return to insulin in high dosage.

Of the 14 diabetics still maintained on an appropriate diet and chlorpropamide, only 1 is taking more than 0.5 g., and it is possible that those taking less may eventually be controlled on diet alone. 3 of the patients who later responded satisfactorily suffered considerable nausea, anorexia, and burning epigastric pain until the dose was reduced.

Reasons for discontinuing treatment.—The hypoglycæmic effect was inadequate in 6 cases (16%). Intercurrent infection or other illness made it imperative to return to well-tried and predictable methods of treatment in 4 cases. In 7 new diabetics when chlorpropamide had been used for initial control, diet only was the method of final choice. Since my earlier brief report to the International Diabetes Federation in Dusseldorf in July, mentioning the toxic effects we had observed, 4 other cases have occurred on low dosage of the drug. Nausea, anorexia, and vomiting were unpleasant in 15 patients, and in 9 of these vertigo was severe and nystagmus was demonstrable. Dermatitis occurred in 2 patients, associated depression and insomnia was particularly marked in one man, although he gave full credit to the drug for having rid him of his glycosuria. One woman persevered but eventually admitted that however much she disliked having injections of insulin it did not make her feel sick like the tablets. A man of 72 who had been transferred from tolbutamide to chlorpropamide with moderate success for three months suddenly began to vomit and continued for three days until the drug was completely withdrawn.

It is possible that these symptoms may be more severe in ambulatory patients than in a trial conducted on inpatients, but such are the conditions in which such a drug would come to be used. It was found that there was a lowering of the total leucocyte count, but when differential counts were performed no reduction of the polymorphs was noted.

Leicester
JOAN B. WALKER

CHILDREN IN HOSPITAL

SIR,—As a psychologist and psychiatrist working in a long-term hospital (mainly orthopædic) for children, we should like to make a few comments on Professor Illingworth's article (July 26) and subsequent correspondence.

Everyone would agree that contacts between children and their families should be maintained as far as is reasonably possible. We cannot lay down any general rules because we simply do not know whether the advantages to the children and parents of frequent visiting outweigh the disadvantages in terms of parental anxiety, neglect of other children and husbands, and the unhappiness of unvisited child patients.

The advocates of frequent visiting at all costs seem to base their claim largely on the careful work of Bowlby et al.[1] But Bowlby and his coworkers were not concerned with the effects of visiting on children in hospital. The implicit assumption by those who base their claims for frequent visiting on Bowlby's findings seems to be that frequent visiting will at least alleviate the separation anxiety of mother and child. This seems commonsense, but it may be an unwarrantable jump (cf. the differing views of experts on this point).

It seems to us legitimate to assume that very frequent visiting of all the children in a long-stay hospital (especially when, as at Chailey, patients come from all over the British Isles) is not possible. O'Connor[2] writes: "There is some danger that too great stress on the dangers of mother-child separation may divert interest from the development of research into the optimal cultural conditions for infant intellectual and emotional growth." Similarly, too much stress on mother-child relationships in hospital may divert attention from developing the optimal conditions for children, particularly in long-stay hospitals. Some children are not in fact permanently damaged by early separation from their homes—36% of Bowlby's sample were rated as "adjusted" after their return from hospital, and many of those rated as "maladjusted" showed milder symptoms than was expected. It has been found that some institutions have a beneficial effect on children. It should perhaps be remembered that the basic assumption underlying the present policy of the school health service for the rehabilitation of maladjusted children in hostels and residential schools is that emotional damage in a child can be repaired away from home.

The effect of deprivation in early childhood may not be as lasting as was at first thought. Work with the rehabilitation of young adult defectives supports this[3] Given a sound environment, children tend to adapt Illingworth stresses the importance of gearing hospitals to the needs of children and makes important suggestions on training personnel and on equipment

---

[1] Walker, J. B. *Brit. med. J.* 1956, ii, 657.

[1] Bowlby, J. Maternal Care and Mental Health. W.H.O. Monograph Series No. 2. Geneva, 1951. Bowlby, J., Ainsworth, M., Boston, M., Rosenbluth, D. *Brit. J. med. Psychol.* 1956, 29, 211.

[2] O'Connor, N. *Acta psychol.* 1956, 12, 174.

There appear to us to be two lines of approach to this problem One is to gear the hospital to all the needs of children, as far as we know these at present, the other is to try to influence public opinion so that there is in general a more favourable attitude towards the physically handicapped It has been shown in America that physically handicapped children tend to show more psychological difficulties than physically normal children, irrespective of their placement, and one reason suggested is society's attitude towards the physically handicapped[4] Bowlby knew that his findings might be at least partially accounted for by the psychological effects of illness per se

To sum up there is some evidence to suggest that some children in hospital are not adversely affected emotionally, that some institutional placements can have a beneficial effect on development, and that unfortunate early experiences (including separation or admission to hospital) do not always have irreversible damaging effects The development of optimal conditions for children in long-term hospitals can do much to minimise psychological trauma The dangers of separation due to illness can be over-emphasised, and so cause avoidable distress to families and to hospital staffs

ACADEMIC REVOKE

SIR,—One of Dr Spencer's conclusions (Aug 30)—namely, that students displaying academic revoke are predominantly of fat and muscular physique—hardly seems to follow from the data which he presents

Referring to his fig 1 he observes "It will be seen at a glance how work revokers congregate to the left of the somatotype chart" *Simple counting of the cases to the left and right* of the vertical line yielded 11 revokers to the left, 10 to the right, and 1 on the midline

If it was intended that the left and right were to be taken from perpendiculars to the ectomorphy axis, the figures on my counting are as follows

	Revokers	*Other psychiatric cases*
Ectopenic	13	26
Ectomorphic	9	52

This table yields a χ^2 of 4 79, which is significant at the 0 05 level,[1] and which confirms Dr Spencer's claim of an association between a fat and muscular physique (ectopenia) and the tendency to revoke This, however, is true of his *particular sample*, and cursory examination of his fig 1 as well of the above table makes it clear that his population of psychiatric cases is predominantly of ectomorphic physique Any group of cases of normal physique could therefore be expected to differ from the non-revoke part of his sample

If Dr Spencer wished to determine whether his revokers were predominantly of ectopenic physique the appropriate comparison would seem to be

	Revokers	*Expected numbers (on a 50 50 basis)*
Ectopenic	13	11
Ectomorphic	9	11

This table yields a χ^2 of 0 73, which indicates roughly a 40% probability[5] of obtaining a greater proportion of ectopenics on subsequent sampling of a population, where the true incidence of ectopenics and ectomorphics is equal Hence we cannot conclude that the revokers tend to be any more ectopenic than ectomorphic, and must conclude, on the evidence presented, that they are of normal physique in these respects, as contrasted with the other types of psychiatric cases

Similar considerations could well apply to the relationship between academic revoke and extroversion If extroversion is associated with ectopenia, and intraversion with ectomorphy, then a group of normal physique could be expected to be more extroverted than a psychiatric group of predominantly ectomorphic physique

In conclusion, Dr Spencer has shown that academic revokers differ from other student psychiatric patients in *certain respects It does not follow that revokers would* differ from students in general, in these respects, nor that the correlations would hold good in a general sample of students

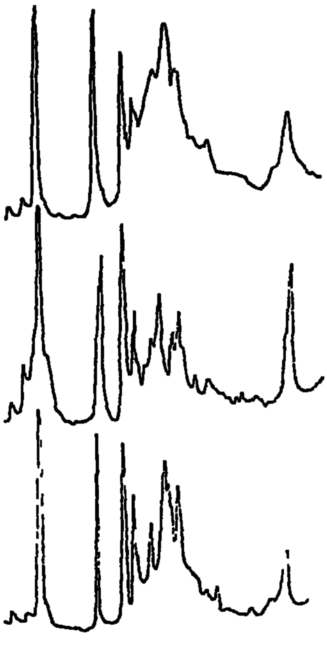
COLIN B HINDLEY

BACTERIAL RESIDUES IN SARCOID LESIONS

SIR,—Mr Nethercott and Dr Strawbridge[1] stated that they had demonstrated mycolic acid in extracts of sarcoid lymph-node This identification was based in part on the acid-fast nature of the extract and in part on a spectroscopic similarity between the extract and a substance called wax C of the human strain of tubercle bacilli

From experience we have gained in the fractionation of the lipids of many strains of tubercle bacilli and in the identification of the isolated components by means of their infra-red absorption spectra,[2] we feel that insufficient evidence has been presented for the identification of mycolic acid in the extracts of sarcoid lymph-nodes

The infra-red spectrum of wax C recorded in the paper of Nethercott and Strawbridge is readily identified as phthiocerol dimycocerosate and contains no apparent mycolic acid The spectrum of the lymph-node extract is similar to the spectrum of any triglyceride of the type found in lard or butter To further illustrate the lack of specificity of the compound isolated from sarcoid tissue, we have prepared a similar extract from lymph-node in a case where the postmortem diagnosis was acute leukæmia A sample of abdominal fat was also extracted The infra-red absorption spectrum for the lymph-node extract is shown in the accompanying figure together with spectra of phthiocerol dimycocerosate and mycolic acid The spectra of these three substances are sufficiently reproducible for it to be readily stated that they are three distinct substances each of which can be recognised by its characteristic spectrum The spectrum of abdominal fat (not shown) was similar to that of the lymph-node extract



Infra-red absorption spectra of various lipid substances Top, *lipid extract of lymph-node from leukæmic individual*; middle, mycolic acid; lower, phthiocerol dimycocerosate

[1] Nethercott, S E Strawbridge, W G *Lancet* 1956, ii, 1132
[2] Smith, D W Randall, H M, Gastambide-Odier, M M, Koevoet, A L *Ann N Y Acad Sci* 1957, 69, 145

Concerning the identification of the presence of mycolic acid by staining techniques, we have stained by the hot-carbol-fuchsin method the following substances phthiocerol dimycocerosate, butter, petrolatum (M P 52-56°C), carbowax (M P 34-38°C), lecithin, boiled linseed oil, collodion, paraffin, mineral oil, and cholesterol We find that the following substances resist decoloration by acid alcohol and therefore are acid-fast petrolatum (M P 52-56°C), boiled linseed oil, and collodion

On the basis of these observations we believe that Mr Nethercott and Dr Strawbridge have presented insufficient evidence to prove that mycolic acid has been detected in extracts of sarcoid lymph-node

PROTECTION OF GONADS FROM RADIATION

SIR,—The article by Mr Newman in your issue of Sept. 6 on slipping of the upper femoral epiphysis was an interesting reminder of the necessity for taking the so-called lateral (or " frog's leg " position) radiograph in painful conditions of the hip in children

May I, Sir, make a plea for more protection of the gonads from radiation in these cases ?

My practice is to take a normal anteroposterior film without protection, as some of these difficult cases turn out to be an osteochondritis of the ischiopubic ramal junction. All subsequent films, including the first " lateral " view taken, have some screening of the gonads This screening does not detract from the quality and usefulness of these subsequent radiographs All follow-up films of the hip, and the films taken at the time of the pinning operation, should have gonadal screening

General Hospital, Harrogate M. W P WARD

ACCIDENTAL HYPOTHERMIA

SIR,—I have recently seen a case of endogenous hypothermia (rectal temperature 84 5° F) in a woman of 45 years with schizophrenia She had been admitted to hospital with a provisional diagnosis of myxœdema coma I was struck by the similarity of the clinical picture to that described by Dr Emslie-Smith (Sept 6) It would be interesting to know if his patient had a family or personal history of mental illness or if schizophrenia was one of the provisional diagnoses made during the course of her illness

Though the diagnosis in our case was unequivocal from the clinical, biochemical, and necropsy findings, we did, at the time, regard the electrocardiogram with its high-voltage complexes and upright T waves as further evidence against a diagnosis of myxœdema coma Thanks to Dr Emslie-Smith's paper it is now clear that the tracing with its broad-based QRS complexes and J deflections was, in fact, the classical tracing of hypothermia and nothing more It is a remarkable finding that hypothermia should render the electrocardiogram so specific in some respects and yet so non-specific in others that the pathognomonic appearance of euthermic myxœdema coma is lost

Though one can have no real objection to the inclusion of myxœdema hypothermias under the general heading of " accidental ", since the term means happening by chance or undesigned, as distinct from induced or artificial forms of hypothermia, nevertheless one cannot help but have some misgivings on the ground of possible ambiguity The term " accidental " has a certain subconscious association with an accident because an accident is a common cause of an accidental occurrence, and the original cases described under the term were examples of exogenous hypothermia following on some accident, either sudden external trauma or sudden internal catastrophe When one speaks of myxœdema hypothermias one understands endogenous hypothermias, unless stated to the contrary, and in grouping them under the same heading as exogenous hypothermias there is danger, firstly, of thinking myxœdema hypothermias to be of the exposure variety and, secondly, of concluding in general terms about two essentially different forms of hypothermia Particularly is this so in relation to the question of warming

The ever-increasing reports on various types of hypothermia make a classification of the subject desirable and suggest a classification of adult hypothermia on more fundamental lines than induced and accidental Hypothermia may be divided into endogenous and exogenous varieties Endogenous can be subdivided into types due to central nervous dysfunction and types due to endocrine gland dysfunction Exogenous can be subdivided into natural (or spontaneous) and artificial (or induced or therapeutic) Natural can be further subdivided into immersion and exposure types and artificial into medical and surgical types The exogenous hypothermia due to natural exposure would correspond with the cases originally described under " accidental "

Coventry DONOUGH MOYLAN

INDUSTRIAL MEDICINE AND GENERAL PRACTICE

SIR,—I read Dr Keatinge's letter in your issue of Sept 6 with interest because I felt that the leading article in *The Times* of Aug 4 was very special pleading It suggests that the Harlow scheme could be adopted for most towns in which are small industrial units and emphasises the advantage of general practitioners thus looking after their own patients

Harlow is a small new centre with work, home, and doctor closely knit In most areas of this country the scatter is wide Most general practitioners doing industrial work would inevitably be looking after the patients of other doctors In many families today members are registered with different doctors, and in a group practice, which is recommended, a group of doctors look after the same family In this development where does the family doctor come in ?

The Times article makes no reference to the duties of the appointed factory doctor This statutory work accounts for a major part of the time of general practitioners spent in industry, and has aroused considerable criticism, though the work presents unique opportunities for the advancement of health I venture to refer to my own study[1] of this problem, concerning which the King George's Jubilee Trust in their report *Citizens of To-morrow* recorded " it seemed to us that national development might well be based on a pilot scheme of this nature "

Finally, reference is made to the need for whole-time medical officers in the larger firms to study toxic hazards and environmental conditions, but there is no mention of the need for these problems to be met by occupational hygiene laboratories working on a regional basis, preferably associated with a university This has been done in the U S A and other countries Expert advice is then readily available for all doctors working in industry or elsewhere and also for employers and even employees who think their health may be affected by environmental conditions

THE FRONTIERS OF MEDICINE

SIR,—I have read with interest Prof C H Stuart-Harris' article of Aug 30 like those of the celebrated egg, parts of it are excellent, but I resent very deeply his statement "When I was a student, it was common to feel that patients were admitted to the medical wards to lie and rot The great watch-word was 'masterly inactivity' " (Dr Stuart-Harris qualified as recently as 1931) I should like to ask him (a) whether his insult is intended only for the physicians of the hospital where he was a student or for British physicians in general, and (b) whether he thinks that his opinion is widely shared by the large numbers of whole-time professors and lecturers who are now mainly responsible for the training of young doctors

Belfast ROBERT MARSHALL

ATTEMPTED SUICIDE

SIR,—It is impossible for authors to defend themselves against an anonymous review, even if they feel that their work has not received a fair appraisal They have, however, the right to protest against misquotations I am referring to the review (Sept 6) of the book *Attempted Suicide* In this and other books the term " suicidal act " has been used for both suicide and attempted suicide According to your review it was used only for the latter, which is quoted as having been regarded by the authors as not self-destructive No such nonsense was asserted in the book On the contrary, it was made quite clear that every suicidal act aimed at self-destruction but that the suicidal attempt could not be fully understood if this motivation alone was taken into consideration

Sheffield, 10 E STENGEL

*** We much regret that our brief summary of the views of Professor Stengel and Miss Cook should have misrepresented them Most authors will sympathise with him about the difficulty of defence against criticism in review, but this is no greater when the review is editorial than when it is personal Our reviews, like our annotations and leaders, can be challenged —ED L

EFFECT OF INACTIVATED SERUM ON COLD AGGLUTININS

SIR,—From the studies of Boorman and Dodd[1] we learn that human serum can enhance the activity of immune isoantibodies when it is used as a diluent instead of saline Also in other immune systems (immune serum anti-sheep-red-cells or in Rose's test for rheumatoid arthritis) human serum reveals this property I have investigated whether normal human serum retains this property also in the titration of autoantibodies, and I chose the cold agglutinins as more readily titrable

If fresh serum is used instead of saline, the titre of the cold agglutinins increases but little, while if a previously inactivated (at 56°C for 30 min) serum is used, there is a huge increase in the titre (from 1 4000 to 1 16 million in one case, and from 1 1000 to 1 4000 in another)

The use of albumin or human gamma-globulin instead of serum does not bring about the phenomenon Serums devoid of properdin have given similar results, as have also normal serums that have not been inactivated but kept at −20°C for one to two months

Not all human serums show this considerable activation of the autoantibody titre some, in fact, are incapable of producing it, while others increase the titre only slightly

It has not so far been possible to discover whether the phenomenon is due to the presence of an activator or the disappearance of a serum inhibitor any such inhibitor, which disappears at a temperature of 56°C maintained for 30 min. may be represented by a heat-labile fraction of the complement (C^1 or C^2) which is destroyed at that temperature

INTRAGASTRIC INFUSION

SIR,—In 1956, you were good enough to publish a short communication[1] about intragastric infusion in infants with acute dyspepsia

We have now used this method 140 times in infants, mainly for acute gastroenteritis We gave physiological saline, Ringer's or Darrow's solutions, and 5% glucose solution, the amount and proportions being the same as for parenteral infusions Sometimes we added plasma substitutes Sometimes plasma was given intravenously In milder cases gastric infusion was combined with feeding by mouth or through the tube We used polyethylene and rubber tubes, as thin as possible, passed through the nose We have not seen any serious complications, even after leaving the tube in for several days

*The effect on vomiting was striking In severe gastro*enteritis the rehydratation was often slower than by the intravenous route, but sometimes the result was almost equally good In toxic gastroenteritis gastric infusion was used only after improvement had been achieved by intravenous infusion Several times we had to replace the method by the intravenous one, either it was not suitable at all or the composition of fluids was wrong

Intragastric infusion has proved a valuable therapeutic measure, and vomiting of any origin very seldom resists this treatment I should be glad to hear from any of your readers who have had experience of enteral infusions

CARDIAC OUTPUT AND RENAL BLOOD-FLOW IN SEVERE DEHYDRATION

SIR,—It is generally supposed that an inadequate general circulation is associated with a reduction in renal blood-flow which is disproportionate to the reduction in cardiac output Renal blood-flow has been determined in most cases by the clearance technique, though this seems an unreliable method when the diuresis is low, as in dehydration

We compared, in serial simultaneous determinations, the cardiac output (by the dye-dilution technique) and the renal blood-flow (by measuring directly the renal venous outflow) in narcotised dogs dehydrated by ligating the pylorus 72 hours before the experiment The reduction in cardiac output was greater than expected from the fall in arterial pressure, so that the total peripheral resistance had increased As determined by the direct technique there was a small decrease in the absolute value of renal blood-flow and the calculated renal vascular resistance was somewhat increased The decrease in renal blood-flow was nearly proportional to the diminished cardiac output

Thus the renal fraction of cardiac output did not decrease during dehydration, as compared to the renal fraction determined by the same technique in normal dogs On the basis of the *p*-aminohippuric acid clearance and extraction ratio a substantially reduced renal fraction was found The clearance results suggested a nearly total renal ischæmia and an enormous increase in renal vascular resistance

A detailed account of our data is to be published in *Acta medica hungarica*

Obituary

JAMES BENNETT HANCE

K.C.M G, K C I.E, O.B E, M.A, M D Cantab, F R.C S E

Sir Bennett Hance, whose death we announced last week, was already known throughout India as a surgeon and clinician before promotion in 1940 brought him to administrative rank His success in this new sphere was recognised by his appointment as director-general of the Indian Medical Service in 1943 His successful tenure of that post ended with the British withdrawal from India, but he continued his work for both countries as medical adviser to the Commonwealth Relations Office

He was born at Liscard, Cheshire, in 1887, the son of a Liverpool barrister, and he was educated at Oundle School, Cambridge University, and Guy's Hospital After qualifying in 1911 he spent some time in Liverpool as assistant to Prof Blair Bell, who fostered his interest in gynæcology In 1912 he entered the Indian Medical Service with the hope of becoming a teaching gynæcologist on the civil side of the service But the 1914–18 war upset this plan, and after service in France and with the South Persian Expeditionary Force he joined the Foreign and Political Department. As a result he spent the greater part of his service in Waziristan, on the North West Frontier, and in the Princely States of Jodhpur, Rajkot, and Mysore While he was resident surgeon in Mysore his chief hospital was at Bangalore, where he tackled not only his favourite gynæcological problems but also all branches of major surgery, including his latest enthusiasm—orthopædics In 1940 the clinician reluctantly gave way to the administrator, and he entered British India, almost as a stranger, to become inspector-general of civil hospitals in Central India. In 1942 he was moved to Delhi as deputy director-general of the I M S, when his administrative gifts were quickly recognised, and a year later he succeeded Sir Gordon Jolly as director-general

Walter Stoneman

Even in the midst of war Hance recognised the importance of post-war reconstruction, and he was a member of the Bhore Commission on the health services of India He visited the United States to study American methods of medical education, and he returned to India to help to plan the Postgraduate Medical Institute at Delhi After his return to this country his work at the Commonwealth Relations Office was interrupted so that he could advise on the organisation of the health services of Ceylon under the Colombo plan Despite ill health he continued to work steadily and devotedly He died on Sept 5 at the end of an assignment abroad.

He was appointed C I E in 1939, promoted K C I E in 1946, and created K C.M G in 1953

G R McR writes

"Bennett Hance had a zest for life. He was ever vital and full of enthusiasm When I met him first in 1924 in Dera Ismail Khan he was experimenting with a new lamp which he had designed for carrying out blood-sugar estimation by McLean's method, and that only a few months after the introduction of insulin He had just finished a five-hour operation session I saw him again that evening, the floor of his living-room was covered with plans for new dispensaries in his wild remote frontier charge, his table with piles of figures for his annual drug and equipment estimates It was, I found, typical of the man—a day's work measured only by what could be squeezed into it He was an all-rounder, as ready to tackle a cholera epidemic as a Wertheim operation or an iridectomy His years in Persia provided him with a fund of Persian proverbs, which he quoted freely His service in Waziristan first brought him into contact with the wild Pathans, and he became a fluent speaker of Pushtu The Pathan servants whom he engaged there remained in his entourage throughout the rest of his service—strange and fearsome though they were among the gentler minions of Mysore.

"On his retirement from the post of director-general it was recognised that he had been one of the greatest holders of that post, for he had not only coped well with the great immediate problems of war-time India but had drawn up sound plans for reconstruction and progress in post-war independent India—plans which are working well today Over eleven years ago his left lung was removed for proved carcinoma Within three months he was back in harness, touring the world, planning, inspecting, and again planning As medical adviser in the Commonwealth Relations Office his dogged devotion to duty when hardly able to draw breath was marvelled at by all—he was always cheerful His end came suddenly and peacefully, on a brief holiday after an important mission oversea His brother officers will ever be grateful for the trouble he took over their resettlement hosts of students from oversea, patiently interviewed and placed by him for training under the Colombo plan, share that gratitude for the work of Bennett Hance"

By his first wife, Catherine, daughter of the late Dr C L Leonard of Philadelphia, Sir Bennett had two daughters In 1938 he married as his second wife Frau Richildis von Kaan, daughter of Richard von Warton of Vienna, who survives him

WILLIAM MOWLL FRAZER

O B E, M D, M Sc Lpool, D.P.H

Prof W. M Frazer, whose death on Sept. 8 we announced last week, was medical officer of health of the city and port of Liverpool from 1931 to 1953

He was born in 1888 in Liverpool and was educated at Liverpool and London Universities He took his M SC in 1909, but his medical studies were interrupted by the 1914–18 war, during which he served in the King's (Liverpool) Regiment Afterwards he returned to Liverpool University and qualified in 1921 The following year he took the D P H, for he had already chosen public health as his specialty He held appointments as assistant M O H at Blackburn, and as M O H at Dewsbury and Hull before he returned in 1931 to Liverpool as M O H Two years later he was appointed to the chair of public health at the University

His work in Liverpool centred round the city's hospital service, and it was largely thanks to him that at the outbreak of war in 1939 the Liverpool municipal hospitals were able not only to cope efficiently with the heavy civilian casualties of the city but also to help to care for the Service casualties who were brought to the port from overseas

For his work in Civil Defence he was appointed O B E in 1939, and during the war he was responsible for the Liverpool casualty services, together with the billeting services, which were sorely tried during the aerial bombardment of 1940 and 1941 He served on committees set up by the Ministry of Health and the Medical Research Council, and on the health committee of the Association of Municipal Corporations He gave the Chadwick and Newsholme lectures, and in 1942 visited the United States to lecture on public health at the request of the Ministry of Information. A prolific and gifted writer, he will be particularly remembered for his monograph *Duncan of Liverpool* (1947), his *Textbook of Public Health* (the earlier

Particulars, including diagrams, may be had from the general manager of British Legion Industries, Preston Hall, Maidstone, Kent

Royal College of Physicians of London

On Friday, Oct 17, at 3 P M , Sir Geoffrey Keynes will give the Harveian oration His subject will be Harvey through John Aubrey's eyes On Thursday, Nov 6, at 5 P M , Prof K W Donald will give the Bradshaw lecture on heart-disease and exercise On Tuesday, Nov 18, at 5 P M , Dr Mildred Creak will give the Charles West lecture The title of her lecture will be Child Health and Child Psychiatry—*Neighbours* or Colleagues? All the lectures will be given at the college, Pall Mall East, S W 1

Association of Clinical Pathologists

This association is holding a meeting from Oct 2 to 4, at the Royal College of Surgeons of England, Lincoln's Inn Fields, London, W C 2 To commemorate the centenary of the publication of Virchow's *Cellular Pathology* the meeting will include a symposium on the pathology of the cell The speakers will be Sir Roy Cameron, Dr Joseph Bamforth, Dr G R Osborn, Prof Robert Cruickshank, Dr Honor Fell, Prof N H Martin, and Dr A G E Pearse Further particulars may be had from Dr J N Cumings, The National Hospital, Queen Square, W C 1

M R C Travelling Fellowships

The Medical Research Council invites applications for travelling fellowships for 1959–60

These fellowships are intended for graduates resident in this country who have had some training in research in clinical medicine or surgery, or in some other branch of medical science, and who are likely to profit by a period of work at a centre in the United States or elsewhere abroad, before taking up appointments for higher teaching or research in the United Kingdom Fellowships held in the United States will provide maintenance allowances, at rates varying from 3000 to 5000 dollars per annum, and travelling expenses Forms of application may be had from the secretary of the Council, 38, Old Queen Street, London, S W 1, and must be returned by Oct 31

British Postgraduate Medical Federation

The inaugural lecture of the 1958–59 series on the scientific basis of medicine will be given by Sir Edward Salisbury at 5 30 *P M on Thursday, Oct 16, at the Senate House, University* of London, Malet Street, W C 1 His subject will be the influence of botany on health and disease

Assessment and Education of Cerebral Palsied Children

The British Council for the Welfare of Spastics have arranged a conference on this subject for doctors on Saturday, Nov 8, at the Engineering School, University Walk, Bristol Prof A V Neale will be in the chair, and the speakers will include Dr R M Norman, Dr N S Alcock, Dr G E Woods, and Dr A L Smallwood Tickets (17*s* 6*d*) may be had from the secretary of the council, 13, Suffolk Street, Haymarket, London, S W 1

Institute of Diseases of the Chest, London

Clinical demonstrations for doctors will be arranged by Dr E H Hudson on Fridays, from Oct 3 to Dec 12 Open lectures will be given on Wednesdays, from Oct 1 to Dec 10, by Sir Russell Brock, Dr F P Lee Lander, Dr A B Paterson, Dr J R May, Dr F H Scadding, Dr Paul Wood, Dr A M C Macpherson, Mr V C Thompson, Dr N L Rusby, Mr W P Cleland, and Mr Donald Barlow All the meetings will be held at 5 P M , at the institute, Brompton Hospital, Fulham Road, S W 3

Inhaled Particles and Vapours

A symposium on this subject, arranged by the British Occupational Hygiene Society, will be held in Oxford in April, 1960 Further particulars may be had from Mr J S McLintock, Medical Service, National Coal Board, Hobart House, London, S W 1

Society of British Neurological Surgeons

On Wednesday, Oct 22, at 5 30 P M , at the London Hospital, Sir Geoffrey Jefferson will give the first Hugh Cairns memorial lecture He will speak on Sir Hugh Cairns Tickets may be had from Mr D W C Northfield at the London Hospital, E 1

Postgraduate Travelling Fellowships

The governing body of the British Postgraduate Medical Federation is offering a limited number of these fellowships to doctors and dentists Further particulars will be found in our advertisement columns

Medical Protection Society

The annual general meeting of this society will be held at Victory House, Leicester Square, London, W C 2, on Wednesday, Oct 1, at 3 P M

British Society of Dental Radiology

Representatives from the X-ray departments of dental schools and hospitals in the United Kingdom have formed this society under the chairmanship of Dr Sydney Blackman Further particulars may be had from Mr Guy Poyton, X-ray Department, Eastman Dental Hospital, Gray's Inn Road, London, W C 1

Royal Medico-Psychological Association

This association is holding a joint meeting with the Section of Psychiatry of the Royal Society of Medicine, at 1, Wimpole Street, London, W 1, on Thursday, Sept 25, at 5 P M , when Dr W E Barton, associate professor of psychiatry at Boston University, will speak on research in rehabilitation

Section of Psychotherapy and Social Psychiatry.—On Wednesday, Sept 24, at 8 P M , at 11, Chandos Street, W 1, Mr Richard Hauser will speak on community developments and group work in psychiatry

On Friday, Oct 10, at 5 P M , Mr William Doolin will give the opening sessional address of the Faculty of Medicine in the *Firth* Hall, University of Sheffield His subject will be *Is* History Bunk?

On Monday, Oct 6, at 3 P M , Sir Eric James, high master of Manchester Grammar School, will give the inaugural address of the new session to the faculty of medicine of the University of Birmingham, at Queen Elizabeth Hospital, Edgbaston, Birmingham

Postgraduate demonstrations in psychiatry will be held at St George's Hospital Medical School, Hyde Park Corner, London, S W 1, for doctors on alternate Thursdays from Oct 9 to Dec 4 at 5 P M Owing to rebuilding the demonstrations in neurology will not be resumed until the Lent term, 1959

Surgeon Rear-Admiral E T S Rudd has been appointed house governor and medical superintendent of King Edward VII Convalescent Home for Officers, Osborne, in succession to Sir Neil Cantlie

Lieut -Colonel C A Bozman, director of the Wellcome Museum of Medical Science, has been invited by the World *Health Organisation* to join a small team of consultants which is to *visit the* All India Institute of Public Health and Hygiene in Calcutta

Dr B Cinader has been appointed head of the subdivision of immunochemistry in the Ontario Cancer Institute and associate professor in the department of medical biophysics at the University of Toronto

Dr P W Hutton, *medical* specialist at Mulago Hospital, Kampala, Uganda, has been elected president of the Association of Physicians of East Africa

The address on Moral Responsibility in Clinical Research, by *Mr D MacG Jackson*, F R C S , which was summarised in our issue of April 26, has now been published in full for the Christian Medical Fellowship, by the Tyndale Press, 39, Bedford Square, London, W C 1 (pp 20 6*d*)

The annual students' dinner of University College Hospital Medical School *will be held at the* Savoy Hotel, Strand, London, W C 2, on Friday, Oct 24, at 8 P M Application for tickets (£1 12*s* 6*d*) should be made to the hon secretary *of the* students' association at the medical school Postgraduate *demonstrations* will be given at the school on Oct 23 and 24

7048

Cushing's syndrome is a progressive fatal disease with an average duration of five years (Sprague 1953, Plotz et al 1952) The underlying metabolic disturbance is due to excessive secretion of adrenocortical hormones, but the anatomical lesion of the adrenal glands may be a tumour or bilateral hyperplasia Early attempts to control the activity of hyperplastic adrenals by resection proved disappointing

Cushing's syndrome was ameliorated but not abolished by the removal of one adrenal, and more extensive resection was too dangerous in the absence of adequate hormonal therapy (Cope and Raker 1955) However, the introduction of cortisone and hydrocortisone made it possible for patients to survive radical subtotal or even total adrenalectomy Many workers have recorded the abolition of Cushing's syndrome by the removal of at least 80% of adrenal tissue (Sprague 1953, Bishop et al 1954, Beck et al 1954, Coone and Humphreys 1956, Mason 1957) Hernberg (1954) suggested extensive subtotal resection of both adrenals Bishop et al (1954) and Montgomery and Wellbourn (1957) favour complete removal of one adrenal and, at a later date, resection of the remaining gland However, Poutasse and Higgins (1953) considered that both adrenals should be resected at one operation, and if the disease was severe no adrenal tissue should be left

We describe here our experience with adrenalectomy in the treatment of Cushing's syndrome associated with bilateral adrenal hyperplasia, and outline the therapeutic regime which we favour The data on serum-electrolytes and glucose tolerance are drawn from 17 patients with adrenal hyperplasia and 1 patient with Cushing's syndrome due to an adrenal carcinoma on whom special metabolic observations were made (case 1) Special metabolic studies, including nitrogen and potassium balances, were made before operation in 8 patients and after adrenalectomy in 9 instances

Diagnosis

Adrenalectomy, with its immediate dangers and prospect of permanent adrenal hypofunction, should be undertaken only when the diagnosis of Cushing's syndrome is proved beyond doubt First, difficulty may be encountered in adolescent girls who exhibit obesity, acne, pink striæ distensæ, menstrual irregularity, and even a slight rise in blood-pressure There may be some increase in the urinary metabolites of hydrocortisone, indicating hyperactive adrenal function, but the absence of muscle wasting and the presence of generalised obesity help to distinguish this from Cushing's syndrome It is essential to observe these patients, rather than to submit them to unnecessary operation, as the disturbance is transitory and responds to a reducing diet A similar type of benign transient disturbance is sometimes seen in young men In contrast to these conditions, which represent a minor deviation of endocrine physiology, is the adrenogenital syndrome in women, arising in puberty and continuing throughout life Such patients are plethoric, hirsute obese yet muscular, with irregular menstruation and, in later years, benign hypertension Urinary steroid excretion is increased, but this is mainly in the form of 17-ketosteroids However disfiguring the disease, it is not progressive or fatal, and therefore in our view adrenalectomy is seldom justified

The diagnosis of Cushing's syndrome requires investigation of both the disorder of function and the anatomical lesion The disturbance of physiology is apparent from the clinical features The effect of increased protein catabolism (or failure of anabolism) can be directly estimated by a nitrogen balance, but this is not essential Associated metabolic changes equally can be detected by the glucose-tolerance test and radiographic examination of bones (particularly the spine and ribs) for evidence of osteoporosis, spontaneous fracture of osteoporotic bone, especially in the ribs, is common Electrolyte disturbance must be investigated by estimation of serum sodium, chloride, potassium, and bicarbonate Because the electrolyte equilibrium is unstable in Cushing's syndrome, a single reading is unreliable and therefore serum-electrolytes should be measured on several occasions An electrocardiogram provides confirmatory evidence of potassium depletion The diagnostic significance of these metabolic changes will be discussed later

Hypertension is an important feature in prognosis, and requires careful assessment by repeated estimations of the blood-pressure with the patient at rest Full renal function tests, including estimations of blood-urea, creatinine clearance, and urinary urea concentration, should be carried out

Estimation of urinary 17-ketogenic steroids by the method of Norymberski et al (1953) has proved satisfactory, and by this method distinctly raised values were found in all our cases of Cushing's syndrome Nabarro et al (1957) were equally impressed by Norymberski's modified method (Appleby et al 1955) which measures 17-hydroxycorticosteroids Both these methods, however, measure other substances which are not derived from hydrocortisone, particularly steroids with 17 20-diol or 21-deoxyketol types of side chain which are excreted in large quantities in adrenal virilism Hence high values recorded by these methods are not specific for Cushing's syndrome The determination of 17-hydroxycorticoids by the Porter-Silber reaction, according to the method of Reddy et al (1952) does not have this disadvantage, but unfortunately it is less reliable than Norymberski's method (Moxham and Nabarro 1956) The excretion of 17-ketosteroids may be increased, decreased, or normal in Cushing's syndrome, so the level of these steroids is of no value in diagnosis (Butt et al 1950) Moreover excretion of all steroids is subject to considerable diurnal variation in Cushing's syndrome (Birke et al 1956), thus the estimation should be made in several (at least three) twenty-four-hour collections of urine

Anatomical diagnosis is more difficult and should be approached critically It is of advantage to determine the presence and location of an adrenal tumour, but it is not essential and X-ray methods such as presacral insufflation of air are neither completely reliable nor free of discomfort We do not think aortography is justifiable, it is difficult and unreliable in obese patients and may be dangerous In practice we have relied on straight X-ray examination and tomography, combined with intravenous pyelography to outline the position of the kidney A large proportion of tumours can be detected by this means

The final decision about the anatomical lesion is made at operation In hyperplasia both glands are enlarged (combined weights 10 2–26 1 g in this series) If a functioning tumour is present the opposite gland undergoes atrophy The type of lesion can therefore be determined when the first gland is exposed The appearance of a tumour is obvious on inspection If the gland is large, but no tumour is present, it can be assumed that hyperplasia is the cause, if it is small it must be left and the opposite side explored

Preoperative Metabolic Studies

Protein Catabolism

The clinical appearances of the patient are related to factors which may vary independently Thus severity of muscle wasting depends on duration rather than on the level of negative nitrogen balance For example, cases 8, 9, and 10 showed only moderate muscle wasting, and this was confirmed by levels of urinary creatinine within normal limits for their known weights before the onset of the disease Nevertheless, they showed a daily loss of nitrogen between 4 5 and 6 9 g with a normal protein intake, and in cases 8 and 10 the presence of creatinuria confirmed rapid muscle breakdown On the other hand, 1 patient (case 1), in whom Cushing's syndrome was due to an adrenal carcinoma, showed gross wasting and the level of creatinine output was roughly half the expected normal, nevertheless at the time of investigation she was losing only 1 4 g nitrogen daily In other cases the disease may be rapidly progressive in the absence of muscle wasting and without gross increase in protein catabolism, case 5, a girl aged 18, had florid Cushing's syndrome with severe hypertension, yet the mean daily nitrogen loss was only 0 4 g

Repletion of protein stores and stimulation of anabolism is extremely difficult in the presence of Cushing's syndrome The results of high-protein feeding are disappointing, even though the nitrogen balance may become positive at first Thus in case 1 muscle wasting was severe, and nitrogen equilibrium was achieved on a diet containing 56 g of protein , When protein intake was increased to 105 g daily there was a positive balance of 3 1 g of nitrogen daily from the fourth to the eighth day, but from the fourteenth to the eighteenth day she retained only 0 6 g nitrogen daily

We have no data on the effect of high-fat diets in Cushing's disease, but studies were made in a patient with Cushing's syndrome after massive cortisone therapy A daily intake of 140 g had no " sparing " effect on protein catabolism, and the daily nitrogen loss was increased by 1 2 g

Potassium supplements have been shown by Albright (1942) to diminish nitrogen loss in patients with potassium depletion In 1 patient in this series (case 1), increasing the potassium intake to 200 mEq daily was followed by a decrease in urinary nitrogen of 1 3 g daily In another patient (case 5) a moderate increase of potassium intake from 60 to 90 mEq daily was sufficient to correct potassium depletion (as indicated by serum level) and urinary nitrogen fell to 0 5 g daily These results indicate that high potassium intake diminishes nitrogen loss, but this is incidental to the potassium repletion and is not otherwise of value in countering protein breakdown

The known action of testosterone in promoting anabolism led Albright et al (1941) to investigate its value in Cushing's syndrome, and it was found to produce significant nitrogen retention We have studied the effect of testosterone propionate on 1 patient (case 9) in different states of nitrogen balance Before operation he was in negative balance of 4 5 g nitrogen daily Intramuscular testosterone 25 mg daily for five days reduced this to 2 06 g , but it was not possible to reverse the negative balance After adrenalectomy the patient was in positive balance and the same course of testosterone increased this by 2 56 g daily—i e , the anabolic effect was quantitatively similar whether the patient was initially in positive or in negative nitrogen balance The expected potassium retention corresponding to the nitrogen retention during these two periods of testosterone administration should be 6 6 and 6 9 mEq daily The observed diminution in urinary potassium during the two periods was 6 6 and 9 3 mEq respectively, the serum-potassium remaining constant

TABLE I—PREOPERATIVE METABOLIC DATA

Case no	Study	Days of collection	Balance (mean daily)		Glucose-tolerance test blood-sugar (mg per 100 ml)			Remarks
			N (g)	K (mEq)	Fasting	¾ hr *	2 hr *	
1	Untreated	4	−1 4	+15		Diabetic		Serum-K 2 3 mEq per litre
	High K intake	5	−0 1	+80				Serum-K rose to 3 1 mEq per litre
	High protein							
	4th–7th day	4	+3 1					
	14th–17th day	4	+0 6					
5	Untreated	6	−0 4	+3	70	146	150	Serum-K 3 6 mEq per litre
	High K intake	8	+0 11	+20				Serum-K rose to 4 35 mEq per litre
8	Untreated	5	−6 9	−8	66	128	72	Studied during relapse serum-K normal
9	Untreated	5	−4 53	+17	90	124	150	
	Testosterone	5	−2 06	+23				Serum-K normal
	4th week after adrenalectomy	5	+4 24	+19				
	Testosterone	5	+6 31	+28				
10	Untreated	4	−5 2	+3	84	130	102	Serum-K normal
14	"	3	+1 5	—	104	200	132	Serum-K normal
16	"	2	+1 7	−2	80	132	132	Serum-K normal
17	High K, high protein diet, and insulin	4	−5	+30		Diabetic		Serum-K 4 7 mEq per litre Had risen from 3 1 mEq after 3 weeks on high K diet High protein diet only for one week

* After 50 g glucose by mouth

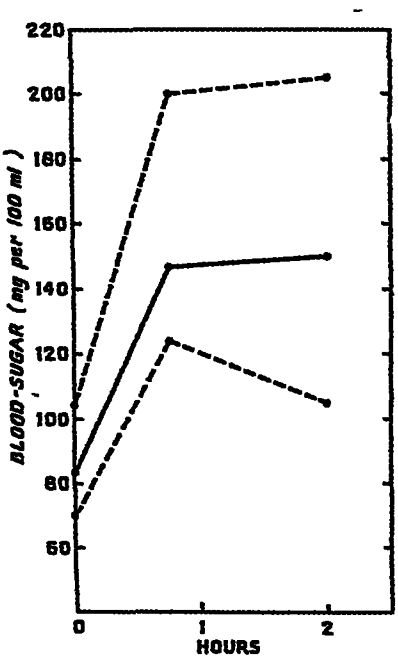

Fig 1—Glucose tolerance in 10 cases with impaired tolerance continuous line mean, interrupted lines, maximum and minimum blood-sugar levels.

Impaired sugar tolerance is a characteristic feature of Cushing's syndrome, and its assessment has some value in diagnosis It is in part related to the degree of increased protein catabolism and in part to the antagonism between hydrocortisone and insulin In this series abnormal glucose-tolerance curves were obtained in 13 of the 18 patients (In case 8 the curve was abnormal before his initial operation, but normal during the relapse of Cushing's syndrome two years later) 3 were typical diabetic curves—1 in the case of adrenal carcinoma (case 1) and 2 in patients with adrenal hyperplasia (cases 3 and 17) The mean curve for the remainder is shown in fig 1 There was no consistent relationship between the degree of decreased carbohydrate tolerance and negative nitrogen balance—which indicates that antagonism between hydrocortisone and insulin is chiefly accountable for the diabetic behaviour in Cushing's syndrome.

Electrolyte Disturbances

Disturbances in electrolyte balance in Cushing's syndrome were first reported by McQuarrie et al (1937) Teabeaut et al (1950) and Sprague et al (1950) noted hypokalæmia with hypochloræmic alkalosis, usually associated with adrenal carcinoma Such a finding is rare in Cushing's syndrome, and in this series was observed only once (table II, case 1) In this patient the serum-potassium was 2 3 mEq per litre, serum-sodium 139 mEq per litre, serum-chloride 86 mEq per litre, and serum-bicarbonate 41 mEq per litre, at operation an adrenal carcinoma was found. Gross muscle weakness was present, and this was abolished when the serum-potassium rose to 3 1 mEq per litre following high potassium intake During the phase of severe hypokalæmia the patient was in positive balance, as in the case recorded by Teabeaut et al (1950) The degree of potassium loss was not related to nitrogen loss, which was only slight Furthermore, although a positive potassium balance was quickly obtained, complete repletion proved difficult since the urinary output of potassium rose following increased intake This would be expected if the potassium loss were due to excessive production of mineralocorticoids—not necessarily due to aldosterone, as Garrod and Tait (1957) found no increase in urinary aldosterone in their cases of Cushing's syndrome with hypokalæmia

TABLE II—PREOPERATIVE SERUM-ELECTROLYTES (MEQ PER LITRE) (ABNORMAL FIGURES)

Case no	Sodium	Chloride	Potassium	Bicarbonate
1	139	*86*	*2 3*	*41*
4	*162*	*108*	4·0	30
5	137	105	*3 6*	30

7	*152*	*112*	4 1	
9	*150*	101	4 8	31
11	*156*	95	5·0	29
12	*163*	*110*	*3 5*	
17	143	95	*3 1*	32

Abnormal readings in italics.

Lesser degrees of potassium depletion were found in 4 of 15 patients with Cushing's syndrome due to adrenal hyperplasia (table II), and again there was no correlation between the rate of protein catabolism and potassium depletion (table I) The serum-potassium levels were below 4 0 mEq per litre, but there was no fall in serum-chloride or rise in serum-bicarbonate. Case 5 was in potassium equilibrium when the serum-potassium was 3 6 mEq Complete and sustained potassium repletion was obtained by increasing the intake by 30 mEq daily The cumulative balance over fourteen days showed a retention of 181 mEq of potassium (the serum level rising from 3 6 to 4 35 mEq per litre) and 53 mEq of sodium, and a loss of 137 mEq of chloride This indicates a loss of intracellular chloride as cellular potassium is restored It is apparent that hypochloræmic alkalosis is a late result of potassium deficiency and that in the earlier stages we find only a lowered serum-potassium Moreover, potassium replenishment is achieved easily when the serum chloride and bicarbonate are normal, but with considerable difficulty at the stage of hypochloræmia In either case, correction of potassium deficiency is an essential preliminary to operation

An abnormally high serum-sodium level was found in 5 of the 15 cases, and, of these, chloride was increased in 3 and potassium was decreased in 1 (table II) This hypertonicity of the serum was probably due to sodium retention Pitting œdema was present in 1 patient, but water retention did not usually balance sodium retention 1 patient (case 10) was studied over a period of seven days during which there was a loss of 4 lb in body-weight and 107 mEq of sodium, yet the serum-sodium rose from 150 to 162 mEq per litre Although salt retention, being less severe, has not the practical importance of potassium depletion, this aspect of Cushing's syndrome should not be neglected

Treatment

Selection of Cases and Operation

We have selected for operation only those patients in whom the diagnosis of Cushing's syndrome was beyond doubt and the disease was definitely progressive Assessment of rate of progress has been based on clinical features such as hypertension, muscle wasting, and weakness, together with the data obtained from metabolic studies of protein catabolism and electrolyte disturbances

Previous work (Sprague et al 1950) showed that at least 75% of hyperplastic adrenal tissue must be removed in order to reverse the metabolic disorder in Cushing's

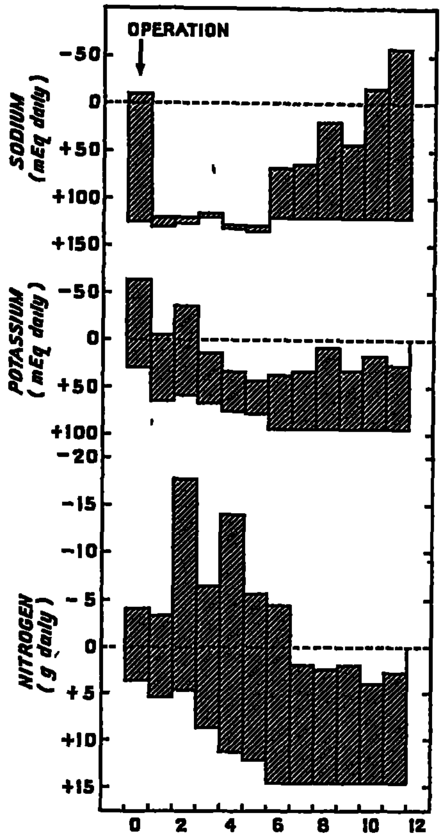

Fig 2—Balance data, case 8a

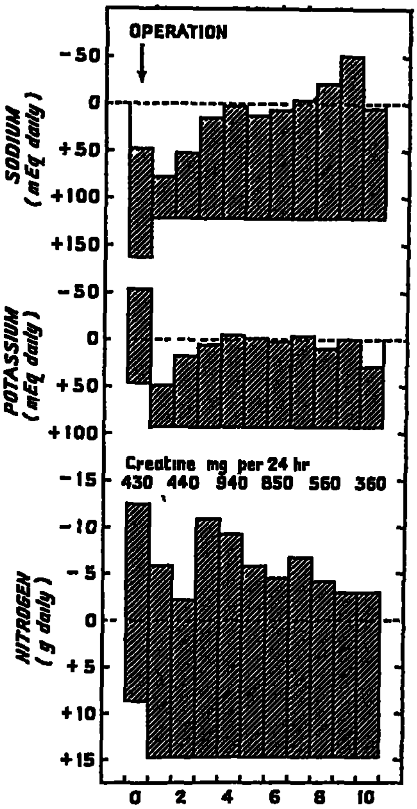

Fig 3—Balance data, case 8b

syndrome There is, however, a very narrow margin between removing enough adrenal tissue to prevent relapse and so much that adrenal hypofunction results In patients under 25 years, and in rapidly progressive, very severe Cushing's syndrome at any age, there is for practical purposes no margin and total adrenalectomy is the operation of choice (Mason 1957) In patients over 45 years, with a more slowly progressive disease, relapse is less likely and subtotal adrenalectomy, leaving only 20–25% of the adrenal tissue, is both adequate and safer

These patients are more likely to suffer from hypertensive vascular disease, which is unlikely to be relieved by the operation and adds to the surgical risk Removal of the adrenals by two operations is often advocated (Bishop et al 1954, Montgomery and Welbourn 1957), and we would endorse this view as regards older patients—especially those with evidence of hypertensive vascular disease In younger patients, however, we feel that, with adequate preparation, the immediate surgical risks of bilateral adrenalectomy in a single operation are less than in two operations, largely owing to the greater hazard of postoperative chest complications associated with two operations

Preoperative Medication

This is needed, first, to correct the existing metabolic disturbance and, second, to cover the sudden deprivation of cortical steroids by adrenalectomy In the rare cases with a diabetic sugar-tolerance curve, insulin will be required The main preoperative therapy is, however, adequate cortisone administration This must be sufficient to maintain the excessive level of circulating glucocorticoids to which the patient has become accustomed, and after operation the dose must be adjusted so that reduction to normal levels is gradual and controlled The dosage scheme is the same for total or subtotal adrenalectomy in a single operation, but differs when the procedure is carried out in two stages In the single-stage operation the dosage of cortisone is far higher than that required for removal of normal adrenals (Mason 1955) and varies according to the degree of preoperative adrenal hyperfunction The following dosage schedule has been found suitable for a one stage adrenalectomy in patients with active progressive Cushing's syndrome

	mg daily
For two days before operation	150
Day of operation and subsequent two days	300
Fourth and fifth day after operation	200
Sixth day after operation	150
Seventh day after operation	100

Cortisone then to be given orally (four doses per day) and reduced every other day to maintenance levels (25–50 mg daily)

Cortisone was not given orally over the immediate period of the operation, because of the

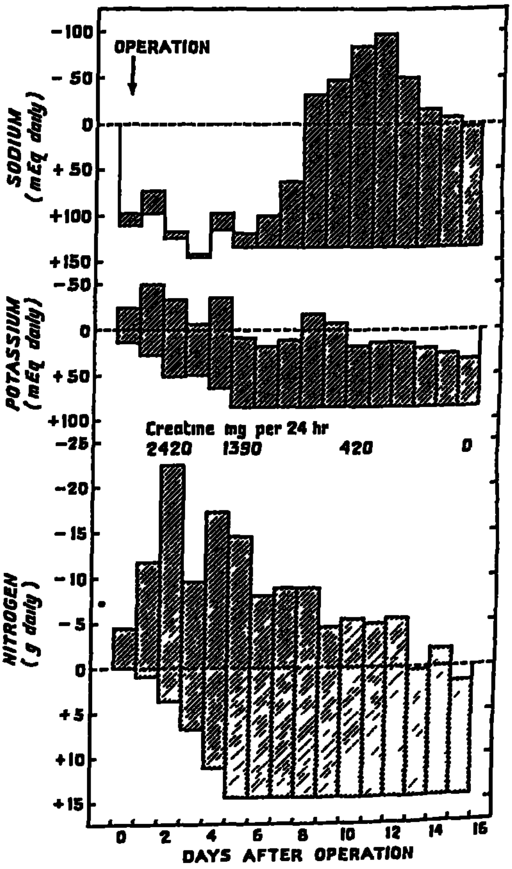

Fig 4—Balance data, case 10

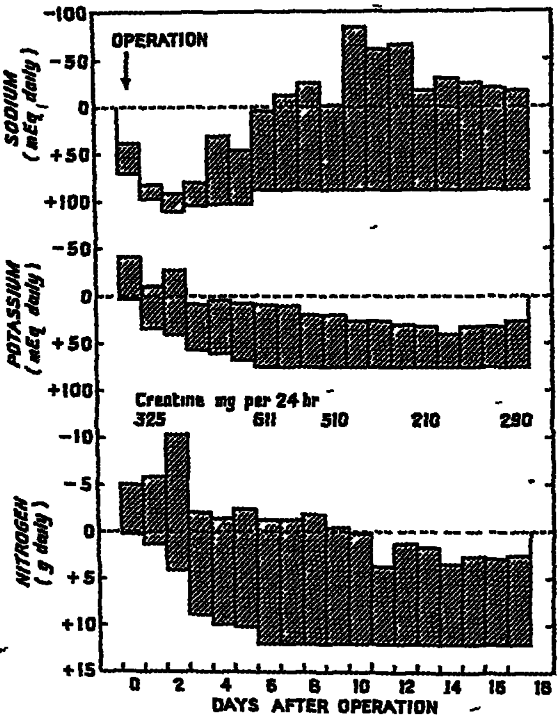

Fig 5—Balance data, case 14.

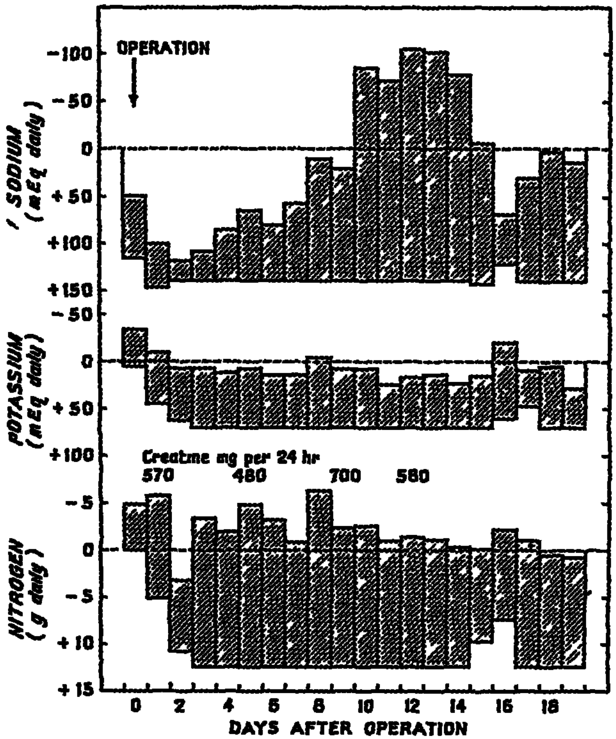

Fig 7—Balance data, case 16

dangers of vomiting and defective absorption Intramuscular injections were given twice daily, starting at least forty-eight hours before operation to ensure adequate absorption Postoperatively the injections were replaced by oral cortisone only when gastrointestinal function had returned to normal

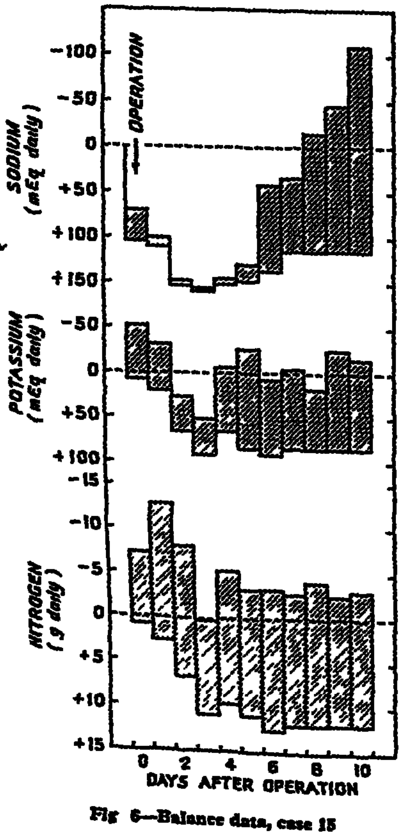

Fig 6—Balance data, case 15

No evidence of postoperative adrenal insufficiency has appeared in patients treated with the above regime Substitution therapy with cortisone alone is sufficient, and the balance data recorded below confirm that there is no need for addition of a mineralocorticoid such as deoxycortone acetate or fluorohydrocortisone in the early postoperative phase

Operative Details

Whether total or subtotal adrenalectomy is to be performed the right adrenal is first removed complete The subcutaneous tissues and muscles are infiltrated with 120 ml of 0 3% lignocaine with 0 5 ml *1 in 1000 adrenaline on each side* If the hypertension is severe the adrenaline is omitted The 11th rib is resected, the diaphragm is divided, and the peritoneum is freely opened The kidney is pushed down and the lung upwards On the right side the liver must be pushed up, and on the left the spleen and pancreas *displaced medially* after division of the peritoneum between spleen and diaphragm On the right the inferior vena cava is located, and then the medial border of the adrenal gland, the wide short vein thus exposed between the two is divided. Sometimes the adrenal is wrapped round and extends behind the vena cava, this part must be dissected, and then the rest from medial to lateral In this way the most difficult part of the dissection is done in a dry field The wound is closed in layers without drainage.

If subtotal adrenalectomy is to be done the whole of the left adrenal is displayed after removing the right An incision is made at a level which would leave $^1/_8$–$^1/_{10}$ of the gland, according to its size If the medial cut surface bleeds and retains its normal colour, its blood-supply is presumed to be adequate and the lateral portion is removed. Biopsy specimens are taken from both kidneys to assess the extent of renal vascular damage

When the patient is turned after the first side is completed, shock may develop even though blood loss has been slight This is due to loss of vasomotor tone in the anæsthetised patient, leading to pooling of blood on the dependent side A blood-transfusion must therefore be started at the end of the operation on the first side

Subtotal resection of each adrenal is in our view inadvisable since, if relapse occurs it is impossible to decide which side should be re-explored. Complete removal of the right adrenal is preferable since hypertrophy of a remnant is more difficult to deal with on this side owing to proximity to the vena cava

Postoperative Care and Complications

On return from the theatre the patient is nursed with blocks to the foot of the bed These are removed when consciousness returns Over the next twelve hours the patient is gradually raised, according to the level of the blood-pressure, to a sitting position An intravenous infusion of 4% glucose and $N/5$ saline is kept running in case noradrenaline or hydrocortisone is needed, and to provide the necessary fluid and electrolytes Intramuscular cortisone is continued according to the regime already described Oral administration of water, electrolytes, or hormones is to be avoided owing to the common development of abdominal distension, presumably as a form of ileus, due partly to the retroperitoneal dissection and partly to the pre-existing metabolic disturbance Gastric aspiration, intravenous fluids, and electrolytes, analgesics, and sedatives may be required until normal gastro-intestinal function is restored During the first few post-operative days fluid intake should not exceed the urine volume plus 1 5–2 0 litres for insensible loss, and not more than 140 mEq sodium daily should be given Larger amounts are harmful and may prolong the ileus Intravenous administration of potassium seems unnecessary

Acute adrenal insufficiency is the earliest and most serious complication We have not observed this since the adoption of the cortisone dosage described above Before this, however, 1 fatal case occurred

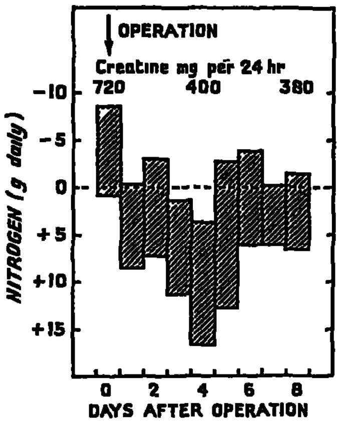

Fig 8—Balance data, case 17

Case 6, a girl aged 16 years, had a severe, rapidly progressive Cushing's syndrome Bilateral subtotal resection of the adrenals was carried out leaving approximately $^1/_{10}$ of each gland There was no incident in her progress until eleven hours after her return to the ward, when she collapsed with a rapidly rising pulse-rate and, rather later, a severe fall in blood-pressure Electrocardiography revealed sinus tachycardia with no evidence of electrolyte imbalance The pulse-rate remained at 160, and the blood-pressure was unrecordable The extremities were extremely cold and pale, there was no respiratory difficulty and no abnormal signs were found in the chest She was mentally alert and very apprehensive, and complained of weakness, vomiting and nausea were absent Her condition remained virtually unchanged until death twenty-eight hours after operation Necropsy revealed bilateral thrombosis of the adrenal remnants but gave no definite indication of the cause of death In this case 75 mg cortisone had been administered intramuscularly daily for two days, and a further 150 mg was injected three hours before adrenalectomy After operation a further dose of 150 mg was injected soon after she collapsed The total water intake, mainly intravenous, was 5 litres in the twenty-four hours after operation, the urine volume over this period was 1 litre Intravenous noradrenaline was given in an attempt to raise the blood-pressure, but despite continued and increasing dosage had no significant effect

Subsequent experience and the reports of other observers clearly indicate that this syndrome is due to inadequate cortisone therapy before and immediately after operation A possible contributory factor was the excessive water intake The failure of noradrenaline to raise the blood-pressure in these circumstances has been noted by others, and the correct emergency treatment is now known to be continuous intravenous administration of hydrocortisone hemisuccinate 50 mg initially followed by 10 mg per hour This is a most effective treatment for acute adrenal insufficiency, and should always be immediately available for patients undergoing adrenalectomy

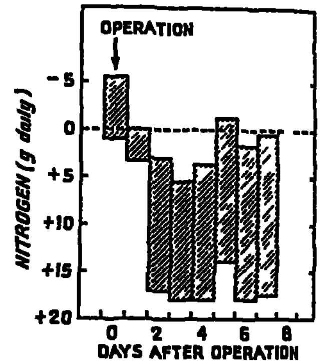

Fig 9—Balance data, case 1

In addition to this acute form of cortical insufficiency, symptoms may arise more insidiously owing to a too rapid fall in circulating corticoids at any time after operation This is particularly likely to occur after radical subtotal adrenalectomy, if the adrenal remnant produces insufficient hormone when cortisone is withdrawn Similar symptoms occur during convalescence if the dosage of cortisone is lowered too rapidly The symptoms include complete anorexia, lethargy, arthralgia, mental depression, irritability, and withdrawal from contact with others (Sprague 1953, Cope and Raker 1955) Electrolyte changes are absent, the pulse-rate seldom rises significantly, and the blood-pressure is maintained, indeed the hypertension of Cushing's syndrome may persist Prompt increase in the dose of cortisone immediately relieves the symptoms

Pulmonary complications are next in severity It is most important at the end of the operation to expand the lungs fully to minimise this risk Hæmothorax and pneumothorax occurred in 2 patients, but responded to appropriate treatment, with complete re-expansion of the lung In 1 patient infection developed in the left subphrenic space, this drained spontaneously and the sinus took a considerable time to heal There is a definite risk of fatal pulmonary emboli (Mason 1957) in those patients who

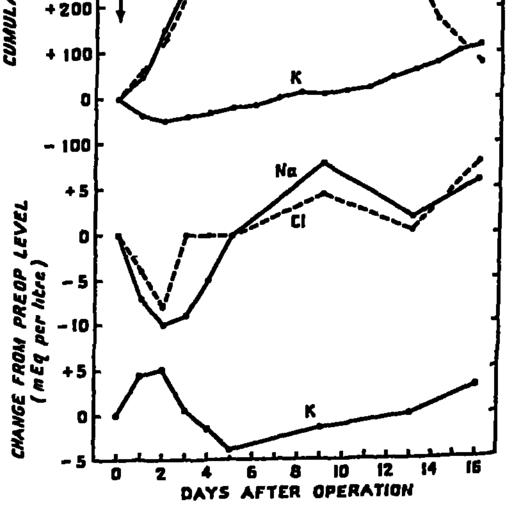

Fig 10—Post-adrenalectomy changes in plasma-electrolytes case 16

are weak and heavy, with a sluggish peripheral circulation and a tendency to bruise easily. Owing to abdominal distension and a liability to postural hypotension adequate postoperative movement is difficult to achieve. 3 patients in this series had a non-fatal pulmonary embolus.

In 1 patient (case 13) the hæmoglobin fell steadily by about 10% each day for five days. After blood-transfusion her hæmoglobin rose and did not fall again. There was no clinical evidence of bleeding in the pleural or peritoneal cavities or of gastrointestinal hæmorrhage, and chest X-ray showed no abnormality. This phenomenon was never explained.

In this series of 17 cases there have been 2 deaths, the 1st (described above) due to acute adrenal insufficiency and the 2nd, in a patient aged 54, due to a combination of hypertensive heart-failure and respiratory failure associated with postoperative pulmonary collapse (case 17). This 2nd case illustrated the operative risk in an elderly patient with poor respiratory and cardiac reserve.

Postoperative Metabolic Studies

Information on the metabolic changes after bilateral adrenalectomy in Cushing's syndrome is scanty. As this has a considerable bearing on treatment, postoperative balance studies were made on 7 patients in this series. (Case 8 was studied twice: (a) at initial operation, (b) at second operation on account of relapse after eighteen months.) The results are illustrated graphically in figs 2–9. The direction and duration of changes in nitrogen, potassium, and sodium balance are similar to those found after any form of operation or trauma (Moore and Ball 1952). In 3 instances (cases 8a and b and 10) nitrogen loss was heavy, and in all it was maximal at the first to third day after operation; positive nitrogen balance was usually achieved by the seventh to twelfth day. Another patient (case 9, table I) showed a strongly positive nitrogen balance several weeks after operation. The degree of nitrogen loss was not directly related to the dosage of cortisone, but was greater than that observed after the removal of normal adrenals (A. S. Mason, unpublished). This is to be expected since the preoperative level of protein catabolism was raised in these patients. There was a rough parallelism between the degree of nitrogen loss and the postoperative output of creatinine, which may be taken as a guide to the lean body mass. Thus case 1 (with adrenal carcinoma) and case 17, who were both grossly wasted and had a subnormal creatinine excretion, showed a very slight postoperative loss of nitrogen.

This increased protein catabolism after operation is qualitatively the same as normal protein breakdown—i.e., 90% of urinary nitrogen is in the form of urea. There was, however, an increase in urinary creatine in the 5 cases in which this was measured after operation compared with preoperative levels. Case 10, with the most negative nitrogen balance, had the highest creatine excretion over a twenty-four-hour period (2.42 g., fig. 4), and in others creatinuria was proportional to the degree of nitrogen loss (see table III). This finding presumably indicates a rapid postoperative breakdown of muscle tissue; a similar but smaller degree of creatinuria occurs after other operations—i.e., this is not specific for adrenalectomy in Cushing's syndrome.

Postoperative potassium loss was slight and a positive balance was achieved after the first three days. Serum-potassium levels remained normal throughout, but usually rose slightly in the first three days after operation.

Changes in sodium and chloride were greater; retention of these persisted until the seventh to the tenth day after operation, when diuresis occurred. During the first forty-eight to seventy-two hours after operation water was retained in excess of sodium; the consequent fall in serum-sodium level was from 6 to 9 mEq. per litre in 7 cases. A typical curve is shown in fig. 10. Nevertheless all these patients were in positive sodium balance. Thus case 15 retained 70 mEq. of sodium in the first twenty-four hours after operation, but the serum level dropped by 6 mEq. per litre. Case 10 retained 431 mEq. of sodium in the first four days after operation, and the serum level fell by 9 mEq. per litre. Sodium retention continued for some days after water excretion returned to normal, so the serum concentration was restored to preoperative levels or above by the fifth or sixth day after operation.

Certain practical conclusions can be drawn from these results. Firstly, measurement of serum levels gives no accurate indication of electrolyte balance. Secondly, there is no need to administer additional mineralocorticoids (such as deoxycortone) over the immediate period of operation. Thirdly, the daily intake of sodium, either intravenously or by mouth, should not exceed 140 mEq. daily. Lastly, the amount of water given intravenously and by mouth during the first two to three days after operation should not exceed the urine volume by more than 1–1.5 litres daily.

These observations apply only to the initial phase of sodium and water retention. In the later period of convalescence the patient requires a high salt intake if electrolyte balance is to be maintained with cortisone therapy. Some patients will undoubtedly require not only cortisone but the continued administration of a mineralocorticoid; fluorohydrocortisone is the most suitable hormone for oral therapy.

Summary

Preoperative and postoperative studies have been made in 17 patients with Cushing's syndrome associated with bilateral adrenal hyperplasia, and in 1 case of adrenal carcinoma. The following conclusions have been reached.

(1) The diagnosis and the progressiveness of the disease must be established beyond doubt before surgery is undertaken.

(2) Both the disturbance of physiology and the anatomical lesion must be considered. There are at present no adequate methods of restoring protein. The electrolyte disturbance must be corrected before operation.

(3) In the younger patients and in those with rapidly progressive disease total adrenalectomy is recommended. In older patients subtotal adrenalectomy is preferred. In the younger patients the operation is carried out in one stage and in older patients in two stages.

(4) The most important item in the immediate preparation for surgery is administration of sufficient cortisone to maintain the excessive level of glucocorticoids to which the patient has become accustomed. To ensure absorption over the time of operation and during the postoperative period the cortisone must be given intramuscularly. Intake of water and sodium must be limited in the immediate postoperative period. The dose of cortisone must be gradually reduced, and later the amount of salt increased.

(5) The most serious postoperative complication is acute adrenal failure. It should be treated by hydrocortisone hemisuccinate, which should always be available in case of emergency. The other complications are ileus, pulmonary embolism, hæmothorax, and pneumothorax.

We are grateful to the physicians of the hospital who have sent us patients, and especially to Prof. Clifford Wilson who has also given us advice in the preparation of this paper, to Mrs. Scott, sister in

charge of the metabolic wards, who did so much to help us with these studies, and to Mr G C Tresidder who operated on one of the cases and has permitted us to refer to this patient

MALIGNANT DISEASE OF THE URINARY TRACT *

SIR ERIC RICHES
M C , M S Lond , F R C S

SURGEON AND UROLOGIST, THE MIDDLESEX HOSPITAL, LONDON, W 1

MALIGNANT growths of the kidney and ureter account for only about 2% of all malignant tumours, yet their clinical presentation is so variable that they often present a difficult diagnostic problem Nevertheless this problem can be solved with almost complete certainty if the right investigations are done These growths show in a striking manner that duplicity which we have come to associate with cancer of the urinary tract whilst some are highly lethal, others follow a relatively benign course The outcome in an individual patient, however, can be foretold with some confidence when all the facts are known

THE KIDNEY

In a nation-wide survey of over 2000 cases collected for the British Association of Urological Surgeons in 1951 parenchymal tumours accounted for about 75% and tumours of the pelvis for about 12% of renal cancers The remainder included some of the most interesting rarities of surgical practice, as well as the Wilms tumours in children My personal series includes 142 cases (table I) The adult parenchymal tumours are solid adenocarcinomas arising in renal epithelial cells they are better known as Grawitz tumours, or by the now discredited name of hypernephromata The pelvic tumours can be either papillary, like similar tumours in the bladder, or solid and either transitional- or squamous-cell

TABLE I—MALIGNANT DISEASE OF THE KIDNEY

Parenchymal carcinoma		89
Secondary carcinoma		1
Sarcoma		1
Pelvic tumour	Epithelial	43
	Sarcoma	1
Tuberous sclerosis		1
Wilms tumours		6
Total		142

Pathology

Whilst there is no proof that a benign renal adenoma can become malignant, there is considerable probability that it does so (Newcomb 1937, Thackray 1953) The possibility of a hormonal factor in the ætiology is suggested by the 2-to-1 preponderance of males over females, chronic simple infection and stone-formation appear to have an influence on the production of the uncommon squamous cell carcinoma of the renal pelvis Papillary tumours of the pelvis may also result from the excretion of carcinogens, but, unless there is unilateral hydronephrosis, this explanation hardly accounts for their usual one-sided distribution

Renal tumours can spread by direct extension and by the lymphatics, but they endanger life chiefly by their predilection for invading venous radicles, the renal vein, and the inferior vena cava

The particular tendency of papillary tumours of the pelvis is to spread to other parts of the urinary tract by the urogenous dissemination either of cells or of a carcinogenic agent

Clinical Features

In a disease with such wide pathological variations it is to be expected that the clinical manifestations will also differ from patient to patient It becomes all the more important to pick out the cardinal symptoms and signs In renal neoplasms there is a classical triad—hæmaturia, pain, and tumour These may be late in appearance, and they may not all be present in any one case, but in most patients they give the first evidence of the disease

Intermittent fever occurs in some cases of both parenchymal and pelvic growth (Griffiths and Thackray 1949, Rowlands 1951) Without necrosis it may be an anaphylactic manifestation (Wright 1922), but, whatever its cause, in my experience it indicates a bad prognosis Loss of weight and anæmia may occur, as in any malignant condition Varicocele on the right side should still be regarded with suspicion, despite the rarity of one which disappears after right nephrectomy

The primary lesion in the kidney may not declare itself until it erodes a calyx or until it attains a large size Before this it has sometimes invaded a vein, and it may have given rise to distant metastases or, quite often, to a solitary deposit

Of skeletal sites the spine heads the list, and sudden paraplegia may be the first indication of renal neoplasm A deposit in a long bone may appear as a pulsating swelling, with the radiographic picture of bone destruction, it can be a teasing examination problem In the lungs the metastases are generally multiple, but solitary tumours have been excised and palpable enlarged lymph-nodes in the neck are sometimes found at an early stage

In at least 4 known cases priapism from a deposit in the penis was the presenting symptom There is, in fact, scarcely a part of the body, including the skin, the thyroid, and the testis, in which a metastasis has not been the first indication of a renal tumour, and because such secondary tumours are so often solitary, their excision may be the proper procedure

The incidence of such a presentation was given as 50%, by Israel in 1896 and as 9% by Deuticke in 1931, but in our series in 1951 it was only 3 2% Such is the effect of modern methods of investigation

The true silent tumours are those which are discovered at necropsy, or when operating for some other condition, such as stone I have seven of these on record

---

* Based on the third Lettsomian lecture for 1958, delivered before the Medical Society of London

Diagnosis

The aim of diagnosis is not limited to the finding of an neoplasm in the kidney It should disclose whether the growth is parenchymal or pelvic, because the treatment of the two differs, and it should determine its operability and the presence of complications It may also give some idea of the prognosis

An opportunity to perform cystoscopy whilst bleeding continues should be seized gratefully If blood is seen coming only from one ureteric orifice the site of bleeding is at once determined. The decoy prostate is eliminated, and that refuge of the destitute, varicose veins in the bladder, is no longer needed

Excretion pyelography is always very informative and, if there has been no opportunity for cystoscopy during bleeding it should be the first major investigation Retrograde pyelography is essential if there is no excretion or poor definition on the intravenous pyelogram In any event it will give a good idea of the extent of the filling defect, and it should serve to distinguish a parenchymal from a pelvic growth.

Aortography

Despite the clear picture it gives, a retrograde pyelogram shows only that there is a space-filling lesion In practice this may be a tumour or a cyst, and, although the diagnosis can often be inferred from the clinical features, the distinction can generally be made by aortography—which is not such a terrible investigation as some seem to think

A parenchymal tumour is vascular the vessels are displaced, and there is usually an irregular deposit of contrast medium in the venous spaces of the growth which gives it a mottled appearance This is known as "pooling" By contrast, a cyst is avascular it shows as a clear area in the nephrogram Pelvic papillary tumours show no specific signs on aortography Solid pelvic tumours are avascular, a pelvic tumour which invades the parenchyma may give rise to an avascular defect in the nephrogram, as may a parenchymal tumour which invades the pelvis

Perhaps the greatest value of aortography will prove to be in the detection of an early carcinoma when the pyelogram is equivocal or the ureter cannot be catheterised We have thus diagnosed a tumour only 15 mm in diameter

Perirenal Oxygen Insufflation

Although rarely needed in the diagnosis of renal tumours, the injection of oxygen by the presacral route can show whether the growth is fixed to its surroundings This may determine the degree of operability and the need for preoperative irradiation.

Treatment and Prognosis

There is general agreement, at least among surgeons, that the treatment of carcinoma of the kidney is nephrectomy with early ligation of the renal vein and removal of the perinephric fat. It is also accepted that in papillary tumours of the pelvis the ureter should be removed with the kidney There is some difference of opinion on the value and place of irradiation in treating kidney cancer A study of the survival-rates has a bearing on these matters (Priestley 1939, Griffiths and Thackray 1949, Riches, Griffiths, and Thackray 1951) it shows that, whilst some of these growths are rapidly fatal, others progress slowly We have tried to analyse the various factors which influence the prognosis in the individual case

1 Histological Grade

The grading is similar to that described for bladder tumours it is based solely on the microscopic appearance The objection has been raised that areas of different grades may be found in the same growth; but just as one bad link weakens a chain, so one area of high malignancy condemns the whole tumour

Of 80 tumours removed by nephrectomy 39 were grade-1, 25 were grade-2, and 16 were grade-3 There were 6 operative deaths 8 further cases were deemed inoperable, and in a fit lady of eighty-seven, with a three-year history of hæmaturia suggestive of a slowly growing tumour, I decided not to operate

TABLE II—5-YEAR SURVIVAL OF PATIENTS OPERATED ON BEFORE JANUARY, 1953

—	Number of cases	Survivals
Total	59	29 (49%)
Grade 1	27	18 (67%)
Grade 2	19	8 (42%)
Grade 3	13	3 (23%)

Table II shows that a rising scale of histological malignancy is reflected in a lower survival-rate. A similar conclusion was reached in 100 patients in the B.A.U.S. series, and Thackray (1957) has shown more recently the same correlation in patients followed for ten years

2 Involvement of the Renal Vein

Macroscopic invasion of the renal vein was seen in 13% of low-grade and 44% of high-grade tumours in this series It can generally be recognised at the time of operation, and an attempt should be made to tie the vein beyond the malignant thrombus It reduces the five-year survival for all grades from 49 to 28%

3 Invasion of the Lymph-nodes

Invasion of lymph-nodes occurred in 6 patients in equal proportions in the three grades 2 lived for about seven years, 1 for four, and 1 for three years Although survival is shortened, these glands respond well to postoperative irradiation If possible, they should be removed with the kidney Excision of recurrent invaded glands in the neck is also worth while. Ultimately 5 of the 6 cases developed other metastases

4 Local Extension

Local infiltration of the perinephric fat, muscles, the colon, the pancreas, or other viscera had taken place in 23% of my cases It was more frequent in growths of high-grade malignancy Its effect on survival is serious, but it does sometimes respond to irradiation.

5 The Presence of Metastases

The existence of metastases is not always a contraindication to nephrectomy This may be required for the relief of pain, hæmaturia, or pyrexia, or on the assumption that removal of the primary growth is likely to make irradiation of the secondary more effective

Metastases were present at the time of the nephrectomy in 9% of my patients Separate excision of a metastasis from the chest wall was possible in 1 patient only, but he is alive nearly five years later Others have had relief from X-ray therapy My figures are insufficient to show whether metastases are commoner with high-grade growth, but I believe that they are It is certain that grade-3 metastases grow more quickly and destroy life earlier

6 The Method of Treatment

So long as the surgical treatment is radical enough, any approach which gives a wide exposure may be adopted

I prefer generally to work through the bed of the excised twelfth or eleventh rib, conversion to the Nagamatsu incision is possible if required. I do not find it easier to secure the renal vein earlier by the abdominal route this is so by the abdominothoracic exposure, but a kidney which can only be removed in this way may not be worth removal In the

B A U S series there was a higher operative mortality after the abdominal than after the lumbar incision

The use of X-ray therapy is controversial There is no doubt that some renal carcinomas are radiosensitive, and there is enough evidence to show that the more anaplastic ones are the more responsive In the larger series (1951) the addition of postoperative conventional X-ray therapy improved the results in all cases, but survival figures were improved most in those, largely of high-grade malignancy, in which the vein was involved Since then I have made it the rule to advise postoperative X-ray therapy for most patients, excluding only those with small tumours of low malignancy, very fat patients, and those who cannot take it The certain indications for it are tumours of high malignancy, venous involvement, lymph-node invasion, or local extension

In a small but increasing number of patients preoperative X-ray treatment has also been given, and study of such patients, known to me personally, has been instructive Some, who would be expected to do badly, have done well

A woman of forty-nine had a tumour which appeared both clinically and on perirenal oxygen insufflation to be fixed After X-ray treatment it became smaller and more mobile, and the oxygen passed around its upper pole The kidney was removed without difficulty though it was a grade-2 growth and the vein was invaded she is alive and well six and a half years later

A man of forty-seven was found at operation elsewhere to have a fixed, irremovable kidney the wound was closed and he was given X-ray therapy I then exposed the kidney again, divided some dense scar tissue, and removed it This was also a grade-2 growth with the vein invaded, but he is alive and well eleven years later

A man of fifty-five had hæmoptysis A shadow near the sixth rib posteriorly was suspected as a carcinoma of the bronchus, but investigations at a chest hospital proved negative A year later he had hæmaturia, and we found a right renal tumour The thoracic shadow was now clearly a destructive palpable metastasis in the ribs He was given conventional X-ray therapy to the rib area and treatment on the linear accelerator to the kidney I then did a nephrectomy The kidney was adherent and on section necrotic, but it was a low-grade tumour with the vein free The lesion in the ribs has shown a progressive diminution in size and apparent calcification in its outline, it is no longer palpable and he is very well at the end of a year

In view of such cases I feel that more use should be made of preoperative radiotherapy, especially if supervoltage machines are available The diagnosis must be certain and aortography may be necessary to make it so If the histological grade or the state of the vein could be known before operation the choice would be easier, but I do not think that renal biopsy is justified for this purpose

I have no doubt that the histological grade of the tumour is the most important single factor in prognosis High-grade malignancy is beyond our control but it may prove possible to mitigate its effects by supervoltage therapy This is our present plan There are of course exceptions to every rule, in this series they are 3 survivors of fifteen years, thirteen years, and eight years, all with anaplastic tumours None had irradiation The vital factor of individual resistance will always have the last word in the argument

RENAL PELVIS AND URETER

The widespread involvement of the urinary tract by papillary tumours is shown by the distribution of the 43 cases in this series (table III)

TABLE III—SPREAD OF 43 EPITHELIAL TUMOURS OF THE RENAL PELVIS AND URETER

Distribution	No
Pelvis alone	15
Ureter alone	4
Pelvis and bladder	9
Ureter and bladder	3
Pelvis and ureter	3
Pelvis, ureter, and bladder	9

These tumours are composed of transitional or squamous epithelium with a few mixed forms Clinically the important division is into the papillary and the less common solid type their behaviour resembles that of the papillary and solid growths of the bladder respectively The squamous-cell tumours are all solid

6 papillary transitional-cell tumours which were histologically benign are included in the series 2 of them affected more than one part of the urinary tract though benign tumours show a higher survival-rate than those described as transitional-cell carcinomas, they have the same age-incidence and the same tendency to spread

Treatment

The treatment of pelvic papillary tumours is nephro-ureterectomy Dealing with the intramural part of the ureter some patients have had a disc of bladder excised, and some, following the advice of Macalpine (1947), have had this part treated by cystoscopic diathermy after section of the ureter flush with the bladder Coexisting or recurrent growths in the bladder have been controlled by cystodiathermy, but 2 patients needed total cystectomy and ureterectomy after the kidney had been removed elsewhere I believe that the kidney tumour usually precedes those in the bladder, and recognition of the renal origin of these bladder growths is essential On the other hand, they may appear in a bladder previously clear as long as two years after nephrectomy and ureterectomy and failure to remove the ureter may result in tumour appearance in the stump What is perhaps most important in the removal of these growths is the avoidance of spill, either of urine or of tumour-cells

A few of the pelvic tumours are radiosensitive In one man with a fixed, inoperable anaplastic growth the mass became smaller, the affected kidney regained some function, and subsequent inguinal metastases disappeared with radiotherapy He died after two years from pulmonary metastases

Dr Thackray classifies pelvic papillary tumours into low and high grades

The 10 patients who lived for five years all had tumours of low-grade malignancy Some have not been available for grading, but out of 18 known low-grade tumours 10 (55%) lived for five years and 4 died earlier from other causes 7 had recurrence or metastasis Of 5 patients with known high-grade growths 1 lived for three years and 1 for two, but none of the others passed the six-month mark 4 of the 5 had recurrence or metastases

Although a widespread distribution of these papillary growths affects survival adversely, it is not so important a factor as the grade of malignancy Low-grade tumours gave rise to metastases in the lungs or liver only after long survival, although local recurrence was more frequent In high-grade tumours bloodborne metastasis was more frequent than local recurrence The solid transitional-cell tumours are much more malignant no patient lived for a year after operation, and metastases in the lungs, brain, skin, or lymph-nodes appeared in 5 out of 7 Radiotherapy did not seem to help them

Squamous-cell *growths were too few to analyse, but they* are known to have a poor prognosis

WILMS TUMOUR (NEPHROBLASTOMA)

That infants and young children can be afflicted by malignant disease of the kidney is one of the cruelties of Nature That it should be of such intense malignancy as is found in Wilms tumour is a refinement of cruelty

In the B A U S series (1951) there were 189 cases of nephroblastoma of which half had occurred between the ages of two and four years Only 8 had been in children under one year, an important fact since it has been shown that the prognosis is better in younger children Boys and girls are affected equally Hæmaturia, which indicates extension to the pelvis, is of bad prognostic import, it occurred in 18% of the patients The renal vein was involved in 8%

Many of these tumours shrink under the influence of radiotherapy, but Higgins and his colleagues (1951) think that these are of higher malignancy and always recur Preoperative *irradiation has a debilitating effect*, and the best reason for its use is to make a very large tumour smaller and easier to remove Gross (1953) used it in alternate cases for a year, but he found that the mortality " skyrocketed "

Early nephrectomy without unnecessary manipulation is indicated It should be followed by postoperative irradiation, starting as soon as possible after operation

Many observers think that survival of eighteen months to two years implies cure, but metastases have been found as late as five years after nephrectomy and local recurrence after eight years In the 189 cases we collected the three-year survival was 26%

The most informative figures are those of the Boston workers (Gross and Neuhauser 1950) They are given in table IV

TABLE IV—" CURE " RATE OF CASES WITH WILMS TUMOUR (GROSS AND NEUHAUSER)

—		Patients under 1 yr	Patients over 1 yr	All ages
Period A	1914–30 27 cases (4 cures)	42 8%	5%	14 9%
Period B	1931–39 31 cases (10 cures)	71 4%	20 8%	32 2%
Period C	1940–47 38 cases (18 cures)	80%	43 3%	47 3%

In period A nephrectomy alone was used.
In period B the transperitoneal route was the rule, but anæsthesia and preoperative and postoperative care had improved greatly
In period C postoperative X-ray treatment was added
The term " cure " indicates a two-year survival free from recurrence.

In a few cases, 3 6% according to Scott (1956), the condition is bilateral

CONCLUSIONS

I hope it is evident that throughout the urinary tract there are two main types of malignant disease Results of treatment cannot be compared without saying whether the tumours were solid or papillary, and whether they were anaplastic or differentiated There will also be some which were intermediate

Though this general survey is based on personal experience, it must be obvious that I owe a great debt to my teams of assistants throughout the years My colleagues have collaborated generously, and I owe especial thanks to Prof B W. Windeyer, to Dr A. C. Thackray, and to Dr C G Whiteside Mr Cowan, the records officer, has checked my figures and made the tables *I must finally express my deep gratitude to* my former chief, Sir Gordon Gordon-Taylor, for stimulating my interest in the surgery of malignant disease

INTRA-ARTICULAR THERAPY IN RHEUMATOID ARTHRITIS

COMPARISON OF HYDROCORTISONE TERTIARY BUTYL ACETATE AND HYDROCORTISONE ACETATE

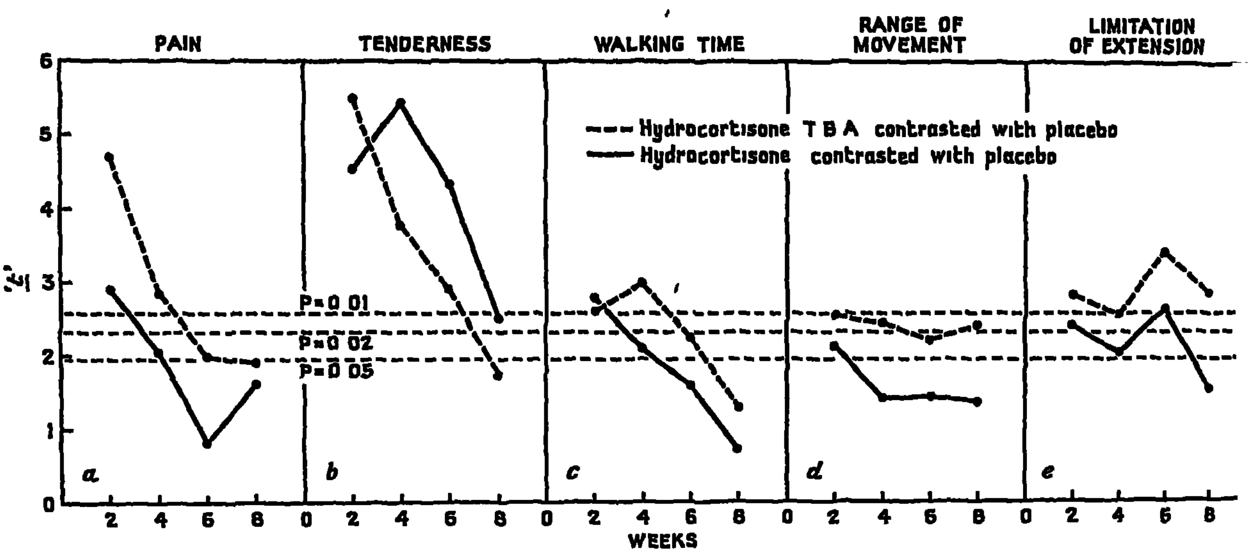
THE intra-articular injection of hydrocortisone acetate, introduced by Hollander et al (1951), is generally regarded as of value in the treatment of rheumatoid arthritis Most patients derive subjective benefit but the effect is usually transient In 1955 a less soluble ester, hydrocortisone tertiary butyl acetate (T B A.), was developed for intra-articular therapy with the claim that its anti-inflammatory effects were more pronounced and of longer duration Hollander et al (1955) found that of 92 patients with rheumatoid arthritis, 62 experienced greater relief and 49 longer benefit from hydrocortisone T B A than from hydrocortisone Duff (1956) stated that of the different chemical forms of local hydrocortisone the T B A preparation was probably the most effective Contradictory results were reported by Zuckner et al (1956), who found no difference in antirheumatic response between the two compounds None of these studies were made in strictly controlled conditions We report here the results obtained by a double-blind crossover trial designed to evaluate these drugs Each patient received both compounds as well as placebo and thus served as his own control

Design of Trial

The clinical material comprised 24 patients with rheumatoid arthritis whose principal disability arose from involvement of the knees In 13 both knees were treated, giving a total of 37 joints suitable for trial on the evidence of active inflammatory changes No patient was accepted whose treatment within the previous two months had included systemic or intra-articular steroid therapy, symptomatic treatment remained constant throughout the period of study which was conducted under outpatient conditions



Comparison of effects of hydrocortisone T B A and hydrocortisone Horizontal axis shows *four* two-week periods after each course treatment Vertical axis shows significance of difference between means of each measurement (t)

a, Effect on pain Significant improvement lasted *four* weeks *after* hydrocortisone T B A and two weeks after hydrocortisone

b, Effect on tenderness Significant improvement lasted six weeks after hydrocortisone and hydrocortisone T B A

c, Effect on walking time Significant improvement lasted four weeks after hydrocortisone T B A and two weeks after hydrocortisone

d, Effect on range of movement Probably significant improvement lasted eight weeks after hydrocortisone T B A compared with on barely significant improvement for two weeks after hydrocortisone

e, Effect on limitation of extension Significant improvement lasted eight weeks after hydrocortisone T B A, and 6 weeks after hydrocortison

The trial consisted of three courses (hydrocortisone, hydrocortisone T B A, and placebo) each of four fortnightly injections, with eight weeks' rest between treatments Dosages of hydrocortisone T B A and hydrocortisone were 25 mg (1 ml) Placebo (1 ml) was the vehicle used as the suspending and preserving agent for the T B A compound The order of courses in each patient was randomised from a master sheet on which names were entered consecutively Injections were given by one of us (G N C) and assessments made every two weeks throughout both the injection and rest periods by the same physician (V W) The nature of the injections was unknown both to the patient and to the assessor

The fortnightly assessments comprised measurements of erythrocyte-sedimentation rate (E S R) walking time over 75 yards, range of joint movement and limitation of extension determined by a goniometer (judgment of joint movement by eye must introduce an important source of error and should be abandoned in favour of more accurate measurement), tenderness (graded 0 = none, 1 = slight, 2 = definite, 3 = patient winces, 4 = withdrawal and/or exclamation), pain (graded 0 = none, 1 = slight on walking, 2 = pronounced on walking, 3 = pain at rest, 4 = severe pain at rest)

Radiographs of the knees were obtained before and after the trial

Results

6 patients failed to complete the trial 1 defaulted after the second course of injections, 4 required admission to hospital after two courses had been given because of deterioration of arthritis, and 1 developed unrelated disease soon after the trial began Withdrawals were scattered evenly throughout the random groups

The specific data (walking time, &c) derived from the first assessment in each treatment period were compared with the same measurements made at the four assessments in the succeeding eight-week rest period Changes in pain and tenderness were evaluated from difference in grading, changes in walking time and joint movement were estimated as a percentage of the pre-treatment measurements, change in limitation of extension w recorded as a percentage of maximal joint range (145° In this way the effect of treatment, both immediate an sustained, was calculated for each of the three treat ments in every patient The mean change for eac group (hydrocortisone, hydrocortisone T B A, and placebo between pre-treatment assessments and each of the fou post-treatment assessments was analysed by conventiona statistical methods (difference of means of unpaire data)

Pain

Significant relief of pain lasted four weeks in patient who had received hydrocortisone T B A, compared wit two weeks in patients who had received hydrocortison (fig *a*) Though greater relief was experienced fro hydrocortisone T B A than from hydrocortisone th difference was not significant at any assessment

Tenderness

Significant improvement in joint tenderness laste six weeks with both drugs Probably significant improvement was still present at the eighth week after hydrocortisone (fig *b*) The difference between the two drug was not significant

Walking Time

Significant benefit lasted four weeks after hydrocortisone T B A, compared with two weeks after hydrocortisone (fig *c*) Except at the first assessment, improvement was greater in patients who received hydrocortisone T B A but the difference between the two treatments was not significant

Range of Movement

Probably significant improvement lasted eight weeks after treatment with hydrocortisone T B A Improvement from hydrocortisone was barely significant at the second week and thereafter became insignificant (fig *d*) There was no significant difference between the two drugs

Limitation of Extension

Significant improvement lasted eight weeks after hydrocortisone T B A compared with six weeks after hydrocortisone (fig 6) There was no significant difference between the two drugs

E S R

There was no significant change in E S R as a result of treatment Throughout the period of study there was a gradual rise in mean E S R which was unaffected by the order in which treatments were given.

Subjective Assessment

The 18 patients who completed the trial were asked to state which course of injections had helped them most 6 preferred hydrocortisone T B A, 4 placebo, and 1 hydrocortisone 7 ranked hydrocortisone T B A and hydrocortisone equal and preferred these to placebo

Complications

2 patients experienced local exacerbation of arthritis, lasting one and three days, after injections of hydrocortisone T.B A 3 patients developed deep-vein thrombosis in the injected leg (2 after hydrocortisone and 1 after placebo)

Discussion

This trial was planned to assess the comparative value of hydrocortisone acetate and hydrocortisone T B A in the local treatment of rheumatoid arthritis Improvement from treatment was measured by fortnightly assessments of pain, tenderness, walking time, range of movement, and limitation of extension On these criteria both drugs showed a significant advantage over placebo Except in the case of joint tenderness, hydrocortisone T B A gave greater improvement which was of longer duration than that from hydrocortisone, but the difference between the effect of the two drugs was not significant in any instance It is possible, but unlikely, that larger numbers might show a more definite benefit that would support the claims made for the greater effectiveness of hydrocortisone T B.A Hydrocortisone had a slight advantage over the T B.A preparation in relief of joint tenderness, but this also was not significant. The random order in which the three courses of injections were given neutralised the expected advantage of first treatment and could not be held to account for the differences observed

There was no consistent or significant change in E S R that could be ascribed to the effect of any particular treatment, so local improvement was presumably independent of any systemic action No important side-effects were encountered apart from transitory post-injection exacerbation of symptoms in 2 patients after injection of hydrocortisone T B.A

The conflicting claims made for the relative effectiveness of intra-articular injections of hydrocortisone and hydrocortisone T B A (Hollander et al 1955, Duff 1956, Zuckner et al 1956) almost certainly reflect failure to conduct trials under controlled conditions Fearnley et al (1956) described a pilot study of intra-articular procaine and hydrocortisone acetate in rheumatoid arthritis which explored the possibilities of a crossover design for evaluating differences between drugs Similar methods, with the additional advantage of a double-blind procedure, have been used in this investigation Such conditions are an essential prerequisite for the proper assessment of treatment in a disease where bias and chance have so commonly led to favourable reports on remedies now discarded

Summary

The effects of intra-articular injections of hydrocortisone acetate and hydrocortisone tertiary butyl acetate (T B A) have been studied in 24 patients with rheumatoid arthritis whose main incapacity arose from involvement of the knees

Each patient was given three courses of injections (hydrocortisone, hydrocortisone T B A, and placebo) in random order Each course consisted of four injections at fortnightly intervals, with eight weeks' rest between courses Pain, tenderness, walking time, range of joint movement, and limitation of extension were assessed every two weeks Neither the patient nor the assessor was aware of the nature of the injections in any course

Both drugs showed a significant advantage over placebo Improvement was generally greater and of longer duration with hydrocortisone T B A. than with hydrocortisone, but the difference was not statistically significant

We are indebted to Messrs Merck, Sharp & Dohme for a generous supply of hydrocortisone T B A We are grateful to Sister P R Benson and her nursing staff for their cooperation

DELETERIOUS EFFECT OF INTRA-ARTICULAR HYDROCORTISONE

UNIVERSITY DEPARTMENT OF CLINICAL MEDICINE,
GENERAL INFIRMARY AT LEEDS

IN a controlled trial of intra-articular steroid therapy in rheumatoid arthritis, both hydrocortisone acetate and hydrocortisone tertiary butyl acetate (T B A) were found to give significant clinical improvement lasting several weeks (Chandler et al 1958a) Four injections of each drug and four of placebo were given into the knees over a period of forty-eight weeks during which physical grading and functional capacity were measured every fortnight Both drugs showed a significant advantage over placebo, but we were disturbed to find that, despite the generally good clinical response to injections of hydrocortisone and hydrocortisone T B A, radiological deterioration, sometimes considerable, had occurred in the knees of over half of patients so treated We report here the radiological findings and consider the possible mechanism by which deterioration occurs

Investigation

Radiographs of the knees (anteroposterior and lateral) were obtained before and after treatment in the 18 patients who completed the trial Twenty-five joints were injected and the X-ray appearances graded into five categories of severity for each feature of the rheumatoid

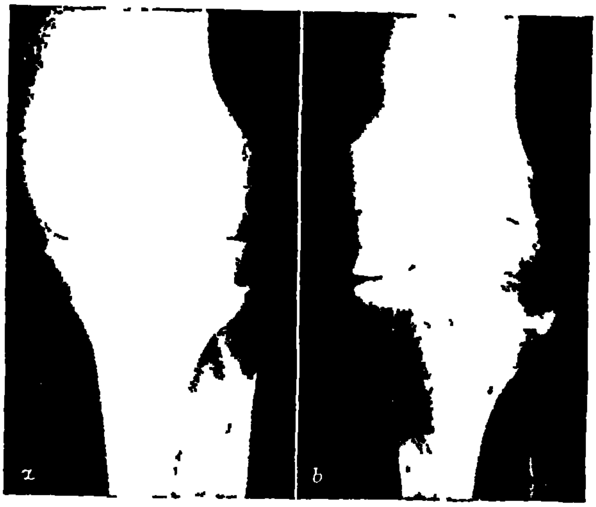

Fig 1—Case 5: Radiographs of left knee (*a*) before and (*b*) after treatment Second radiograph shows distinct increase of joint damage by erosion, and further loss of joint space

process (porosis, lost of joint space, and erosions), together with an overall rating as suggested by Kellgren and Lawrence (1957) 13 joints—just over half—showed radiographic deterioration Definite worsening occurred in 8, distinct deterioration in 3, and severe deterioration in 2 (table I)

Examples of deterioration are shown in figs 1 and 2

The data were then analysed to determine whether any correlation existed between the clinical response to treatment and radiological deterioration The changes in the initial and final clinical assessments of joint conditions were graded into three categories—improved, unchanged, worse—and considered in relation to radiological change

TABLE I—RADIOGRAPHIC FINDINGS IN 18 CASES BEFORE AND AFTER TREATMENT

Case no	Joint	Grade before treatment				Grade after treatment				Deterioration
		Porosis	Joint space	Erosion	Overall grading	Porosis	Joint space	Erosion	Overall grading	
1	L	2	1	0	1	2	1	2	2	+
2	R L	1 1	1 2	1 1	1 1	1 1	2 2	2 2	2 2	+ +
3	L	1	2	2	2	3	2	3	3	+
4	R	3	2	2	2	2	2	2	2	0
5	R L	2 1	4 3	4 1	4 2	3 4	4 3	4 4	4 4	0 +++
6	R L	3 3	2 2	1 0	2 2	3 3	2 2	1 0	2 2	0 0
7	R	1	2	2	2	2	2	2	2	0
9	R	1	0	0	0	1	0	0	0	0
10	R L	2 1	3 2	1 0	2 1	2 2	3 2	2 1	3 2	++ +
11	R	3	2	2	2	2	3	3	3	++
14	R L	2 2	1 2	1 2	1 2	2 2	2 2	2 2	2 2	+ 0
15	R	2	0	1	1	2	0	2	2	+
16	L	2	0	0	1	2	0	0	1	0
17	R L	0 0	0 0	0 0	0 0	0 0	0 0	0 0	0 0	0 0
19	R	2	2	2	2	2	2	3	3	+
20	R L	1 2	2 2	1 1	1 1	3 3	2 2	4 3	3 3	+++ ++
23	L	3	3	4	4	3	3	4	4	0
24	L	2	0	2	2	0	0	2	2	0

Grading of radiographic changes 0=normal, 1=doubtful, 2=minimal, 3=moderate 4=severe.
Deterioration in joint condition 0=none, +=definite worsening, ++=much deterioration, +++=gross deterioration

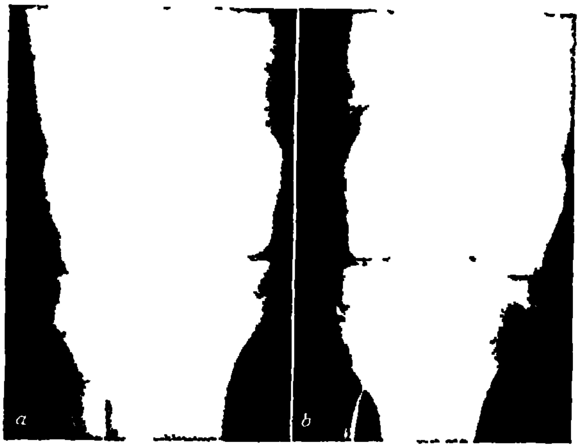

Fig 2—Case 20 Radiographs of right knee (*a*) before and (*b*) after treatment Second radiograph shows further notable increase in joint damage by erosion

Fig 3 shows that, as might be expected, the group of patients without radiological deterioration contained a larger number of good responses (10 out of 12 joints) than the group in which deterioration had occurred (7 out of 13) The difference was not important (χ^2=·80, P=0·4) and indicated that there was no significant association between overall clinical response and radiological change In each radiological group 1 patient deteriorated clinically

The three most useful measurements of joint function (pain, walking time, range of movement) were considered separately in relation to radiological change Immediate and sustained improvement in clinical status after each course of treatment with hydrocortisone and hydrocortisone T B A were estimated at the second and sixth weeks Mean improvement in pain was calculated from the difference in grading, mean improvements of walking time and range of movement were estimated as a percentage of pre-treatment measurements Since the curve of improvement in these criteria of joint function followed the same pattern after both treatments the data deriving from the effect of each were considered together in relation to radiological change (table II)

There was no significant difference in the amount of improvement of pain and range of movement between the group of patients in whom radiological deterioration occurred and the group in whom no such change was observed At the second and sixth weeks after treatment relief of pain was greater in the group who showed radiological deterioration, but the difference was not significant Only in respect of walking time was a significant difference apparent A tendency at the second week to greater improvement in the group with radiological deterioration became definitely significant at the sixth week (P=0·01) Range of movement showed greater improvement in the group without radiological worsening of disease, though this was not significant

Discussion

Undoubtedly the intra-articular injection of hydrocortisone and hydrocortisone T B A into the knees of patients with rheumatoid arthritis leads to clinical im-

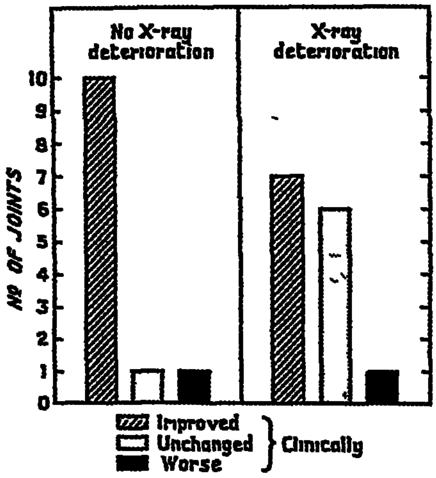

Fig 3—Relation of clinical response to radiological change.

provement which is encouraging to the physician and appreciated by the patient. Nevertheless in this series of patients who took part in a controlled trial of these compounds radiological deterioration, often considerable, was observed in over half This disturbing and unexpected finding could be held to result from inevitable progression of disease, but two pieces of evidence are contrary to such an interpretation First, the group of patients who showed unmistakable and often severe radiological deterioration on the whole fared only slightly less well, judged by clinical criteria, than the group in whom no advance in the radiographic features of arthritis occurred Secondly, the experience in the Empire Rheumatism Council (1955) trial of aspirin and cortisone in rheumatoid arthritis was that radiological deterioration in the large joints did not occur in a year's observation, with scarcely an exception radiological changes were limited to the small joints of the extremities The implications from the present study are definite Intrasynovial injections of hydrocortisone and related compounds either failed to halt or, more usually, accelerated pathological changes, despite the clinical relief enjoyed by the majority of patients

This apparent paradox of worsening disease in the face of clinical improvement was subjected to further investigation by analysis of the data derived from the various clinical assessments of joint function. No significant association could be traced between the effects of treatment on pain and range of movement in the two groups of patients with and without radiological progression of arthritis An important difference between the groups was, however, apparent in respect of walking time, a trend towards greater improvement at the second week after treatment in the group with deterioration became very significant at the sixth week It must be concluded that the principal effect of treatment in this group has been the attainment of a standard performance beyond the capacity of the joint. The discrepancy between the effects on pain and walking time in the two groups is probably more apparent than real Walking time is to be preferred as a measurement of improvement, for the quantification of pain is notoriously imprecise The fact that it was not until the sixth week after treatment that improvement of walking time became significant in the group with radiological deterioration suggests that sustained relief rather than immediate improvement is the damaging factor

TABLE II—EFFECT OF TREATMENT ON JOINT FUNCTION RELATED TO RADIOGRAPHIC CHANGE

Factor	Weeks after treatment	Mean improvement		Standard error of difference of means	P
		Group with X-ray deterioration	Group without X-ray deterioration		
Pain*	2	1·52	1·29	±0·38	<0·6
	6	0·88	0·67	±0·37	<0·6
Walking time†	2	7·0	4·7	±2·43	<0·4

Range of movement	2	7·7	8·5	±2·96	<0·8
	6	6·1	6·6	±3·09	<0·9

* Improvement in pain calculated by difference in grading

† Improvement in walking time and range of movement calculated as a percentage of pre-treatment measurements.

‡ Definitely significant.

The evidence is very convincing that treatment with intra-articular hydrocortisone compounds is potentially dangerous, its very success carries with it a threat of accelerating joint destruction We have reported elsewhere (Chandler et al 1958b) the production of a virtual Charcot's arthropathy in an osteoarthritic hip treated over an eighteen-month period by monthly injections of hydrocortisone This patient had obtained almost complete relief from pain when treatment was discontinued Indeed the symptomatic benefit experienced by patients may lead to a vicious circle of dependence despite worsening disease By a local mechanism in which functional improvement and relief from pain are the most important features, it seems likely that interference with the normal protective processes natural to inflammatory disease encourages a degree of weight-bearing and mobility which is inherently traumatic. Dangerous progression under these circumstances might well be expected, and has been our experience in this study Strict radiological supervision is essential if intra-articular administration of hydrocortisone and related compounds is to retain its place in the rehabilitation of the chronic rheumatic patient

Summary

18 patients with rheumatoid arthritis whose chief complaint was ascribed to involvement of the knees completed a trial of the effects of intra-articular injections of hydrocortisone acetate and hydrocortisone tertiary butyl acetate 25 knees were treated

Radiographs of the knees were obtained before and after the trial, in which physical grading and functional capacity were assessed every two weeks

Radiological deterioration was observed in 13 joints despite significant clinical improvement in the majority

Only in walking time was a significant difference apparent between patients who deteriorated radiologically and those who did not Improvement in walking time was significantly greater in the first group This group also showed a somewhat greater relief of pain after treatment, but this difference was not significant

The chief cause for radiological progression was the encouragement of a damaging level of performance by interference with a normal, locally protective mechanism.

We are indebted to Prof S J Hartfall for permission to study these patients and for helpful criticism.

BARIUM MEAL AND FOLLOW-THROUGH

A C Glendinning
M B Belf, D M R D
RADIOLOGIST, BROMLEY GROUP OF HOSPITALS, KENT

Haudek (1912) observed that, if there was a considerable residue in the stomach six hours after a contrast-medium meal, this was good evidence that a disorder was present This was not a particularly challenging or arresting statement, but for some reason it struck a responsive chord A six-hour residue Here was something concrete—or very nearly concrete, bearing in mind the horrible mixtures of bread and bismuth which patients were called upon to swallow in those distant unlamented days In the succeeding forty-four years all else has changed, but not the concept To a surprising extent the medical profession is still ready to shake a wise head over a six-hour residue and set about putting it to rights Haudek may have been largely forgotten but this is his true memorial—a niche in the hall of fame as lasting as that other niche which shows with such satisfactory clarity on the lesser curves of our gastric-ulcer patients

In modern practice the six-hour residue has a significance in that it is linked with the idea of a barium meal and follow-through This is a very easy examination to ask for but not at all an easy examination to do, and it is one which is regarded with something like dismay in most X-ray departments If it is merely a matter of recording the presence or absence of a six-hour residue this is one thing, but generally the follow-through has no such clear-cut target The doctor demanding it may have made the request simply in the form of a catch-phrase, but even when this is not the case the intention is often obscure and it is left to the radiologist to do as little or as much as he thinks fit Such examinations are difficult to fit into appointment systems, and in departments where several radiologists are employed on a sessional basis the want of continuity is an additional drawback The short answer is that "barium meal and follow-through" when asked for in a routine way is likely to prove an unsatisfactory business

Radiologists have recognised this from early times, and various routines have been introduced in an effort to get over some of the difficulties One such is the double-meal technique, of which Haudek himself was an advocate but which as often as not has no other result but to make confusion worse confounded

These are perhaps somewhat controversial views, but they are held by many radiologists and for this reason it was thought worth while to see how far they could be supported and to examine critically the significance of Haudek's six-hour residue Not much has been written on these lines Shanks (1952) makes several references to Haudek's work and concludes that a six-hour residue, if of considerable size—say one-fourth to one-third of the meal—is usually of pathological import, but that even then it may be due merely to gross hypotonia and ptosis This is fair comment, but it still leaves the issue somewhat in doubt It was with this feeling that the work on which the present paper is based was undertaken

Method and Material

In the circumstances it did not seem appropriate to introduce a new routine, since the object was to check the usefulness of the ordinary everyday examination From the start, however, a special ledger was opened and all the patients in the series were put through the greater part of the procedure recommended by Shanks (1952) for full barium-meal examination The first object was to determine the percentage of cases in which there appeared to be a "significant" six-hour residue and later to follow these cases up In the course of this it was hoped to gain further insight into the true place of the follow-through in gastrointestinal investigation

In all, a thousand barium meals were studied and, making allowances for re-examination, 866 patients were included All were seen and screened before and during the taking of the meal Five basic films were exposed—two erect, an erect serial of the duodenal cap, one supine, and one prone—and if necessary other films as indicated All the patients were seen and screened again after an hour, and finally films were taken at six hours A routine dose of 'Raybar' 16 oz was given Patients were seen fasting No food or drink was allowed between the immediate examination and the one-hour stage, but, again following the technique described by Shanks, a light lunch was permitted before the six-hour film

When this plan was made it was recognised that the routine was not exhaustive It was, however, chosen as a compromise which would see the head of the meal into the proximal colon in most cases and allow a view of the often-important ileocæcal region In a large number of cases the meal was followed further in an attempt to study the whole colon, but since this was not always done the results were not included in the record

Cases referred were in three categories—(1) hospital inpatients, (2) hospital outpatients, and (3) patients referred direct by their family doctors—and thus gave a very representative cross-section

Results

A preliminary simple breakdown is interesting (see table I)

The initial examinations in the series were done between August, 1949, and April, 1951, and by a coincidence Gryspeerdt (1951) was working on a similar series at the same time but to a somewhat different end In the composition of the two sets of patients the main difference is that, whereas at Bromley the sexes were very evenly matched (439 males as against 427 females), in Gryspeerdt's series males outnumbered females in the proportion of 692 to 308 Gryspeerdt found positive evidence of abnormality in 53 9% of his cases, compared with 55 6% in my own series Taking the most common disease conditions the findings compare as shown in table II

In the present series a percentage of 9 4 diagnosed as query duodenal ulcer may seem unsatisfactory, but in the interpretation of what are after all no more than shadows there must often be room for doubt In barium-meal examinations many duodenal caps appear at some stage or other perfectly normal and can be classed as such The absolutely unequivocal recognition of a duodenal ulcer

TABLE I—PRELIMINARY BREAKDOWN

Disorder	Whole series	Male patients	Female patients
Nil	387	165	222
Gastric ulcer	59	31	28
Duodenal ulcer	210	137	73
Query duodenal ulcer	81	51	33
Carcinoma	17	9	8
Hiatus hernia	32	10	22
Others	77	36	11
Totals	866	439	427

TABLE II—COMPARATIVE FINDINGS IN TWO SERIES OF 1000 BARIUM-MEAL EXAMINATIONS

Disorder	Gryspeerdt (1951)	Present series
Gastric ulcer	17.4%	6.5%
Duodenal ulcer	25.1%	24.0%
Query duodenal ulcer	—	9.4%
Carcinoma	3.3%	1.8%
Hiatus hernia	1.1%	3.8%

is much rarer—as, for example, when an ulcer is shown barium-filled *en face* at the point of convergence of mucosal folds. By far the greater number of duodenal ulcers must be diagnosed on indirect evidence. Often this evidence is perfectly satisfactory, but there still remain the other cases (in this series 9.4%) where a conventionally normal cap cannot be shown and where at the same time a lesion cannot be sworn to. Often minor anatomical variations—for example, of the mesentery or of the gastroduodenal artery—are to blame, or the duodenal loop may be taking an independent course with confusing results.

Despite these minor differences there is quite a lot of agreement between the two series, and the results compare closely enough with those of other workers to echo a general pattern of gastrointestinal frailty.

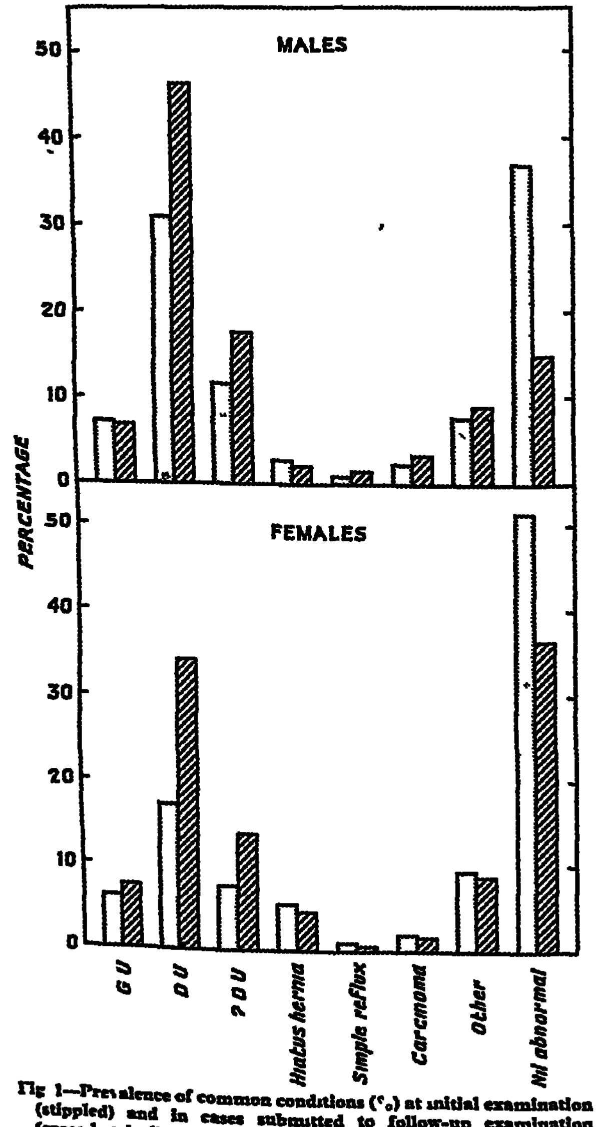

Fig 1—Prevalence of common conditions (%) at initial examination (stippled) and in cases submitted to follow-up examination (cross-hatched)

As regards the specific question of a six-hour residue two special steps were taken in each case. First, when the patient was screened at the one-hour stage the amount of barium remaining in the stomach was roughly estimated. A guess was made (in writing) as to whether or not there would be a significant residue at six hours, and finally this was checked by the six-hour film. For record purposes a quarter to a fifth of the meal remaining in the stomach at six hours was regarded as significant. Admittedly a guess made in this way is not evidence. However, for as long as medicine remains in some degree an art, impressions will be important and it was my conclusion that a practised observer could forecast a six-hour residue accurately in more than 85% of cases. Among those cases in which the residue was found it was clear that slow emptying and pathology did tend to run together in certain conditions. This is shown graphically in fig 1, in which the sexes are treated separately. The figure records the prevalence of the common conditions in the whole series and, alongside, the comparable figure in the six-hour residue cases which later constituted the follow-up.

TABLE III—RESULTS OF A FOLLOW-UP ON 215 PATIENTS WHO HAD EARLIER BEEN SHOWN TO HAVE SLOW STOMACH EMPTYING

Group	Males	Females	Totals
No dyspepsia and cases normal at repeat barium meal	26	44	70
Chronic peptic ulcer	24	28	52
Partial gastrectomy for peptic ulcer	23	9	32
Other gastrointestinal lesions proved at operation	7	8	15
Dyspepsia continuing check refused	—	3	3
Deceased	6	5	11
Failed follow-up	12	20	32
Totals	98	117	215

For both men and women the trend is similar. Duodenal ulcers and query duodenal ulcers constitute a much higher percentage of the total in the excess-residue group than in the series as a whole. Conversely the percentage of normal is much higher (especially in males) in the full series than it is in the follow-ups. Elsewhere there is little to choose. It would seem therefore that only in the duodenal-ulcer cases is there a demonstrable link, and this is, of course, what one would expect.

The Follow-up

Further to the initial analysis outlined above an attempt was made to follow up the excess-residue cases in the hope partly of checking the X-ray diagnosis and partly of assessing progress.

There were 215 follow-up cases—98 males and 117 females. The follow-up was done as a running investigation, some of the patients coming to operation within a few days of being first seen and others having had their further barium meals as late as 1957. Great difficulty was experienced in tracking down many of the patients, and when the search was abandoned in 1957 thirty-two of the original total (12 men and 20 women) had not been traced. Of the others the survivors were either re-examined by barium meal or communicated with directly or through their family doctor. A large group—15 men and 25 women—had no dyspepsia and sensibly refused another barium meal, but only 3 refusals were met with from patients still complaining. The large number who came to gastrectomy is striking. The main findings are summarised in table III.

Of the total followed up 38 2% were regarded as not having any significant upper-gastrointestinal abnormality The percentage of males in whom findings were normal was little more than half the comparable percentage in females This is probably no more than an echo of the fact, demonstrated by the initial examinations, that slow stomach emptying is more of a female than of a male characteristic The percentage of normals was smaller for both sexes in the follow-ups than in the whole series, as is shown in fig 2

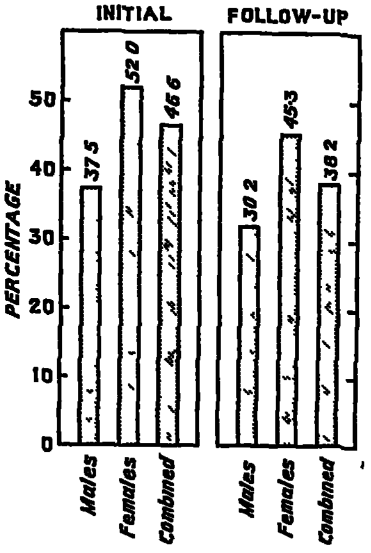

Fig 2—Prevalence of normal findings (%) at initial examination and in cases submitted to follow-up examination

Discussion

The results of this investigation may be considered first in relation to slow stomach emptying and secondly in relation to the usefulness of follow-through techniques in general

Slow Emptying

Stomach emptying certainly cannot be said to follow any simple set of rules The anatomy is straightforward enough and can be checked in any textbook, but physiology is very different The digestive work of the stomach is secretory and motor, and any study which fails to take both these factors into consideration is not likely to be conclusive This is emphasised by Hunt and Spurrell (1951), who claim that for a true estimate of gastric function a simultaneous quantitative record of secretory and motor activity during the passage of a meal is necessary They state that this can be made by their “ serial meal ” technique in which a series of standard meals is given, each being terminated by total withdrawal after different intervals of time Where the barium meal clearly fails is in providing a record only of the results of stomach motility

As well as being complex in nature, stomach emptying is difficult to control artificially, largely because of the whim of the pyloric sphincter From a practical standpoint it would help greatly in the interpretation of equivocal pyloric abnormalities if relaxation could be brought about and quick emptying assured Roka and Lajtha (1950) claim to achieve this control by means of oral procaine, but personal experiences with this method have been disappointing Methanthelinium (‘ Banthine ’) has a limited application, and Chapman et al *(1953)* have shown how barium follow-through examinations can be used to check and compare the action of drugs (including methanthelinium) on the propulsive activity of the stomach

In the final analysis Haudek may be said to be broadly supported Organic disease, especially peptic ulceration, will lead to slow emptying because of either spasm at the pylorus or stenosis There is one other well-defined group of slow emptiers these patients have the normal hyposthenic type of stomach, but with a relatively immobile high duodenal cap—a cap, in fact, in the position usually described in textbooks of anatomy If this group are kept up and about, emptying may be very slow, but their normality is shown by the ease with which emptying will occur in the recumbent position, especially prone and oblique

From the point of view of everyday practice it is important to know that delayed emptying from whatever cause can usually be recognised at the initial examination, or failing this within an hour Further radiographs to prove the obvious are unnecessary

The Follow-through

Quite a strong impression has been gained from a study of this series that little help towards a diagnosis is ever likely to come from screening or films at one hour or at six hours Furthermore when the follow-through is carried on to twenty-four or forty-eight hours it is usually equally disappointing The examination is *wasteful of time, energy, and material, and might well be* abandoned as a routine test

This judgment calls for some elaboration in view of the long-held belief that a barium meal is not complete unless it is carried through to show the large intestine The arguments for this have been well stated by Douthwaite (1956), who claims that, because a barium enema overfills the colon and irons out irregularities by hydrostatic pressure, the large bowel may be better viewed in the late stages of a meal But the introduction of the tannic-acid technique for barium enemata (Harper and Hughes 1950) has altogether changed the picture In the tannic-acid enema the stage which matters is the after-evacuation stage where there is no distension of the colon On these films in a high proportion of cases the whole length of the gut from cæcum to a point in the sigmoid can be viewed empty, contracted, and in spasm with every fold of the mucosa illustrated Nothing approaching this in usefulness is ever seen at follow-through, and if necessary air replacement can be used for additional contrast and detail The stage of filling is of little interest unless the lesion is gross—and then, of course, almost any technique will suffice With this big advance ready to hand there is no longer any need to guess at abnormalities in the colon on the follow-through appearances

It is not intended here to advocate new techniques but rather to ask for the rational use of old ones The gastrointestinal tract is too various and complex to yield up its secrets easily to any one blunderbus method A barium meal should obviously be done when abnormalities of œsophagus, stomach, or duodenum are in question For the small intestine there is likewise an appropriate technique Finally, when it comes to the colon there is only one proper complement to sigmoidoscopy, and that is a barium enema To some this may seem a long way round, but far more often than not it will prove the shortest way home

Summary

A series of a thousand unselected barium-meal examinations has been studied with a view to assessing the frequence and importance of delayed stomach emptying

In this series 98 males and 117 females were found to have a significant stomach residue after six hours, and these patients have been followed up Slow emptying is linked with duodenal abnormalities

The barium follow-through is often time-consuming and unhelpful It should not be done as a routine, and

in particular, it should never be relied on for the demonstration of the large bowel.

I have to thank the X-ray, almoner's, and outpatient departments at Bromley Hospital for assistance with the follow-up, and, in particular, Mrs C. Davies, Miss N E King, and Sister B Latchford. I received welcome assistance from Mrs L. F Steele in compiling the tables and figures

SERUM-CHOLESTEROL LEVELS AND BLOOD-PRESSURE OF ALASKAN ESKIMO MEN

E M. Scott
Ph.D Minnesota

Isabelle V Griffith
B S Wisconsin

Dale D Hoskins
M.S Oregon State

Robert D Whaley
M.D California

From the Arctic Health Research Center, Public Health Service, Department of Health, Education, and Welfare, Anchorage, Alaska

Although the Eskimo has been cited as a race which has little atherosclerosis and yet consumes a high-fat diet (Sinclair 1953), it has also been pointed out that the incidence of atherosclerosis among Eskimos is actually unknown (Keys et al. 1957), since necropsies have almost never been performed Indeed, in Alaska, most Eskimo death certificates are signed by persons other than a physician Furthermore, a large proportion of Eskimos do not have a high-fat diet (Scott 1956)

Both the serum-cholesterol level and the blood-pressure level have been associated with the incidence of atherosclerosis (Dawber et al 1957) The present study was designed to determine whether these variables are different in Eskimo men from what they are in white persons living in the United States We also wanted information about local differences in the diets of Alaskan Eskimos so that we could decide on the areas where the relationship of diet to cholesterol level might be most profitably studied

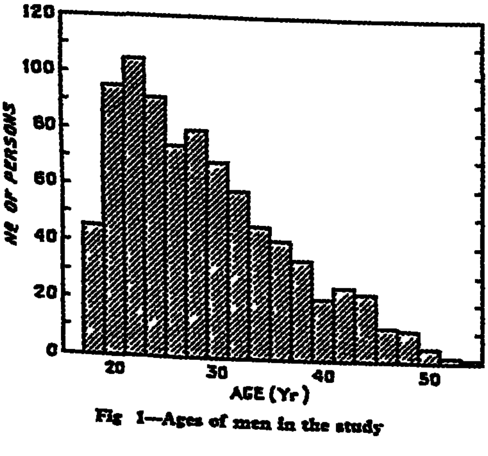

Fig 1—Ages of men in the study

CHOLESTEROL LEVELS OF ESKIMO MEN

Age	No of subjects	Mean	Cholesterol level	
			Standard deviation	Range
17–19	90	187 8	39 1	109–386
20–24	247	201·9	3[illegible] 9	123–302
25–29	162	219·7	47 1	122–373
30–34	144	219·7	39 1	133–329
35–39	91	233 3	40·1	166–405
40–44	58	234 5	45 5	131–354
45–49	26	243·4	51·4	179–378
50–53	4	200·5		186–217

Methods

The subjects were 842 Eskimo men between the ages of 17 and 53 who were members of the Alaska National Guard No physical examination is required for membership of the Guard, although persons with gross physical abnormalities or active tuberculosis are usually excluded It was estimated that 80% of the subjects were full Eskimos Included also were one small group of 28 Aleuts and another of 19 Athabascan Indians Cholesterol was determined on non-fasting serum by the method of Abell et al (1952) Twenty-two of the serum samples were sent to the laboratory of the Heart Disease Epidemiology Study, Framingham, Massachusetts, where independent determinations gave results 4 6±1 2 mg per 100 ml higher than our results Blood-pressure was determined in the sitting position

Results

The mean cholesterol level of all persons tested was 214 4 mg per 100 ml with a standard deviation of 40 9 (see table) There was considerable variation of mean cholesterol level depending on geographic location (fig 2) The highest mean level was 293 mg (S.D 64) in 11 subjects, while the lowest mean level was 171 (S D 32) in 15 subjects Men from four of the forty-three villages studied had mean cholesterol levels significantly higher than the average of all Eskimos, while representatives of ten other villages had significantly lower levels, using a 20-to-1

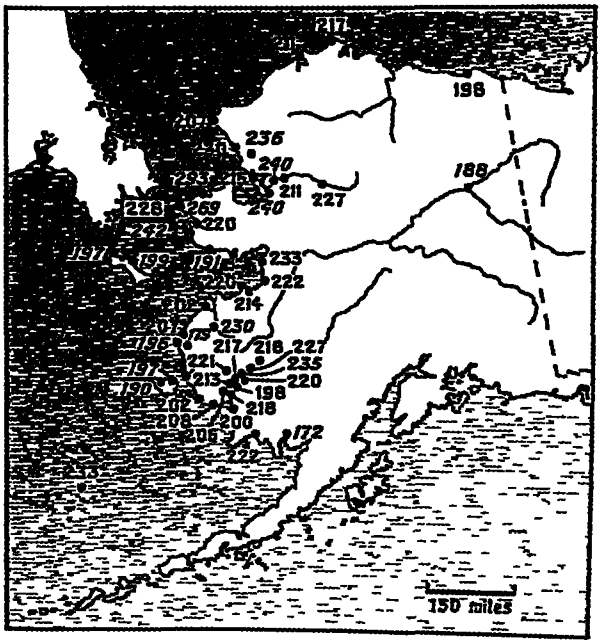

Fig 2—Mean cholesterol levels of men in the study Figures in italics are significantly higher or lower than the mean of all subjects.

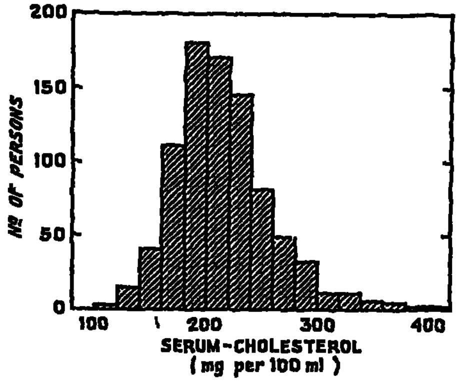

Fig 3—Cholesterol levels of Eskimo men Median level is 202 mg per 100 ml

criterion of significance The numbers in italics in fig 2 represent these villages However, the only generalisation possible from this figure is that northern Eskimos have higher cholesterol levels than southern Eskimos (*217 8±2 0 mg* per 100 ml as opposed to 210 2±1 9 mg)

There was some dependence of cholesterol level on age (r=0 377) The least squares equation of this dependence was

Cholesterol level=158 8+1 97×age

The results shown in the table resemble closely those obtained in normal men in the United States (Lewis et al 1957) In calculating probability of significance of differences of cholesterol levels, a correction was made for age dependence

Different blood-pressure readings were obtained by different people, and also by the same person on different days Our correction for these possible errors may have minimised actual differences between villages The average systolic pressure found was 126 9, the average diastolic pressure was 74 3, and the average pulse pressure was 52 6 mm Hg In further calculations, the mean of the systolic and diastolic pressures was used The average mean blood-pressure of all men tested was 100 6 (S D 10 1)

Of the 842 men tested, 22 had mean blood-pressures above 125 mm Hg They came from 16 villages, but no village had more or less persons with high blood-pressure than would be expected from random sampling Of the forty-three villages from which 10 or more men were tested, four were found in which the men had average mean blood-pressures significantly higher than the average for all villages In another four, the values were significantly low The values obtained and probability of significance for each of these eight villages were 111 6, 0 003, 106 2, 0 004, 105 0, 0 022, 104 4, 0 008, 96 2, 0 010, 95 9, 0 006, 94 6, 0 017, 91 7, <0 0001 That these differences were real seemed evident, since mean blood-pressures of men from two villages measured by the same persons on the same day were 104 4±1 4 and 94 5±2 5 These two villages, though only 14 miles apart, have a quite different ethnic background, and the populations do not intermingle

There was a low correlation of mean blood-pressure with age (r=0 142) At age 20, mean blood-pressure was 98, while at age 45 it was 104 There was little or no correlation between mean blood-pressure and serum-cholesterol (r=0 066)

Discussion

In the first study of cholesterol levels in Eskimos, Corcoran and Rabinowitz (1937) found these levels to be very low The mean of 27 determinations was 141 mg per 100 ml Subsequent investigations on other small groups of Eskimos (Wilber and Levine 1949, Sinclair et al 1949, Rodahl 1954a, Pett and Lupien 1958) have failed to confirm these low levels, and are in agreement with our results Although Alaskan Eskimos as a group appear to have normal serum-cholesterol levels, the geographic variation in level deserves further study

The measurements of blood-pressure in this study are in essential agreement with, although slightly higher than, those found in a large series of men in the United States (Robinson and Brucer 1939). In any case we, unlike Rodahl (1954b), have found no evidence of unusually low blood-pressures in Eskimos

Summary and Conclusions

The mean serum-cholesterol level of 842 Eskimo men did not appear to be unusual, but there were significant differences in men from different localities in Alaska Measurements of blood-pressure showed much less variation, although here again geographic differences were found

TYPING OF Q-PHASE INFLUENZA-A VIRUS BY SERUM-NEUTRALISATION TESTS IN MONKEY-KIDNEY CULTURES

MARGUERITE S PEREIRA
M B Aberd

From the Virus Reference Laboratory, Colindale, London, N W 9

THE method currently used for typing strains of influenza virus is based on hæmagglutination inhibition by type-specific sera This method is simple and rapid and gives reliable information in the majority of cases It is not, however, satisfactory for certain strains (Q) which have been described by van der Veen and Mulder (1950) These Q strains combine very poorly with the homologous antibody responsible for inhibiting hæmagglutination and give low titres in hæmagglutination-inhibition tests compared with strains in the reactive or P phase When injected into ferrets Q-phase strains do, however, stimulate the production of antibodies which react with strains in the P phase, and Q-phase strains are usually typed indirectly by the preparation of an antiserum which is subsequently tested by hæmagglutination inhibition with a strain in the P phase This method is, however, laborious and wasteful of laboratory animals

Vogel and Shelekov (1957) described an adsorption-hæmagglutination technique for detecting influenza virus grown in monkey-kidney cultures By this technique influenza virus is grown in monkey-kidney tissue cultures to which guineapig red blood-cells are subsequently added The red cells are adsorbed to the infected tissue cells in a characteristic pattern This has been called hæmadsorption By this technique we have obtained

The figures denote the reciprocals of dilutions of sera inhibiting 100 hæmadsorption doses of virus

type-specific serum-neutralisation reactions with strains of influenza virus in both the P and the Q phase

Materials and Methods

Virus strains —Standard strains—Shope, PR8, WS, FM-1, and A/Ned/36/56—were received from the World Influenza Centre Strains isolated in the recent epidemic of Asian influenza were received from various laboratories of the Public Health Laboratory Service, all these strains were isolated in fertile eggs and were received as early passage fluids

Sera —Standard sera for the different type strains employed were supplied by the World Influenza Centre Antisera against some of the Asian-influenza strains were prepared by intranasal inoculation of ferrets with freshly isolated strains

Monkey-kidney cultures —Trypsinised cell suspensions were grown for 5 days in stationary tubes with a medium consisting of 0 5% lactalbumin hydrolysate and 0 5% ox serum in Hanks' solution with 100 units penicillin and 100 µg streptomycin per ml This medium was then replaced by Eagle's medium (1955) without serum, the cultures were inoculated and incubated in a roller drum

Virus titrations —Tenfold dilutions of the virus under test were inoculated in volumes of 0 1 ml into a pair of monkey-kidney cultures After 48 hours' incubation 0 2 ml of a 0 4% suspension of freshly washed guineapig red cells was added The tubes were kept at room temperature for 10 minutes and then examined under the microscope for hæmadsorption The end-point was taken as the highest virus dilution showing hæmadsorption

Serum-neutralisation tests —Serial dilutions of standard sera in 0 5 ml volumes were mixed with equal volumes of a virus dilution containing 100 hæmadsorption doses, incubated for half an hour at 37°C and inoculated into tubes of monkey-kidney tissue These tubes were then sloped in a rack so that the serum-virus mixture was in contact with the tissue cells After half an hour at room temperature the fluid was removed from the tubes and replaced by fresh medium, and the tubes were incubated in a roller drum for 48 hours at 37°C, 0 2 ml of a 0 4% suspension of guineapig red cells was then added to the tubes, which were examined for hæmadsorption. The neutralisation titre was taken as the highest final serum dilution showing complete inhibition of hæmadsorption

Hæmagglutination-inhibition (H I) *tests* —These were performed in 'Perspex' plates using 0 25 ml volumes of serial dilutions of sera treated with cholera-filtrate to remove any non-specific inhibitors of hæmagglutination, 0 25 ml of a virus dilution containing 8 agglutinating doses, and 0 25 ml of a 0 5% suspension of washed fowl cells The serum dilution showing 50% agglutination was taken as the end-point (World Health Organisation 1953)

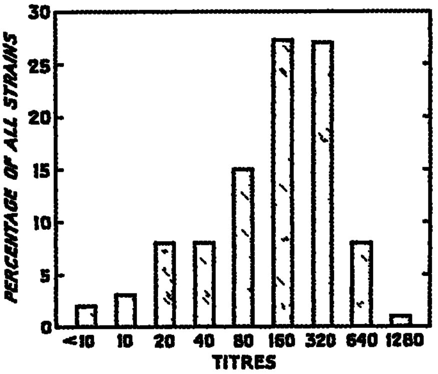
Results

The results of serum-neutralisation tests with standard strains of influenza-A virus are shown in table I Cross-reactions were rarely observed, and except for that between PR8 and WS they were of small degree As in the H I tests crossing was not observed between Asian strains and any of the earlier influenza-A viruses

Table II shows the results of H I tests and serum-neutralisation tests with strains of influenza-A virus in the P and Q phase It will be seen that in the H I tests the Q-phase strains did not combine with antibody in sera prepared in ferrets against either P or Q phase viruses, whereas both P and Q strains combined equally well in the serum-neutralisation tests It is clear from these results that strains in the Q phase may be easily identified by serum-neutralisation without recourse to making a homologous serum The frequency with which Q-phase strains were encountered in 1957–58 is shown in the accompanying figure All the tests included in this figure were done with one of the three Asian-influenza ferret antisera with titres varying between 1/160 and 1/320 when tested against A/Singapore/1/57 21% of 500 strains examined gave titres of 1/40 or less 10 of these have been tested and successfully typed by the hæmadsorption technique described above



Frequency distribution of titres of 500 strains of Asian-type influenza-A virus in H I. tests with A/Singapore/1/57 ferret sera

Preliminary results of work in progress with human convalescent sera suggest that rises in antibody against Asian influenza are detected more frequently by the hæmadsorption technique than by H I tests

Summary

Asian strains of influenza-A virus in the Q or non-reactive phase, determined by the standard hæmagglutination-inhibition test, can be typed fairly simply by a serum neutralisation test in monkey-kidney tissue culture using the hæmadsorption technique of Vogel and Shelekov (1957)

I should like to thank Dr F O MacCallum for encouragement in this work, and Dr A Isaacs (World Influenza Centre) for supplying some strains and sera

HYPERPYREXIA IN ENCEPHALITIS TREATED BY HYPOTHERMIA

Sporadic cases of encephalitis have an uncertain prognosis, the outcome depending partly on the success of prophylaxis and treatment of the complications of the coma One feature of the disease which may cause death is hyperpyrexia A case is here described of encephalitis complicated by rapidly increasing pyrexia in which the temperature was reduced by hypothermia induced by drugs and physical cooling and maintained at a subnormal level until consciousness returned

Case-report

A lift attendant, aged 30, was admitted on Feb 12, 1958 Eight days before admission he had had a febrile illness with sore throat and cough, diagnosed as " influenza " All members of the family had a similar illness at the time After four days he had recovered sufficiently to resume work Two days later he complained of pains in the back and was sent home from work at midday Arriving home he slept from 2 P M to 8 30 P M on a couch, refused food, did not reply to his wife's questions, and then retired to bed He made no complaint of headache That night he was extremely restless in bed, sweated profusely, and shouted several times Next morning his wife was unable to rouse him and noted that his whole body was shaking On her return to the bedroom after summoning the doctor she found him sitting on the floor in a pool of urine, he did not recognise her, nor did he answer her questions He was admitted in a stuporose state

His past history included partial gastrectomy for a duodenal ulcer in 1953 and deterioration of visual acuity in 1954, owing to familial macular degeneration At that time a full neurological examination had been performed by Dr E A Blake Pritchard and ophthalmological examination by Mr C Dee Shapland, these provided very useful records for purposes of comparison Since then he had been able to read only with the aid of a powerful hand lens in addition to glasses

On admission his temperature was 100 4°F, pulse-rate 100 per min , pulse regular, respiratory rate 28 per min He was very agitated and restless, did not reply to questioning but responded to painful stimuli, and greatly resented physical examination He had neck rigidity, trismus, and photophobia His pupils were equal and circular, and reacted to light His fundi showed bilateral macular degeneration, with optic atrophy on the right side, the disc margins were sharp No abnormality was detected in the remaining cranial nerves In his limbs the tone varied from time to time with spontaneous movements, he had continuous muscle twitchings His tendon reflexes were weak and plantar responses flexor His respiratory excursion was noticeably shallow and he was cyanosed

Investigations —White blood-cells 9800 per c mm (polymorphs 70%, lymphocytes 26%, monocytes 4%) Urine normal Chest X-ray normal Lumbar puncture yielded cerebrospinal fluid (C S F) under pressure of 300 mm H_2O (but patient was struggling) containing protein 110 mg per 100 ml (globulin, slight excess (Pandy test)), white blood-cells 31 per c mm (lymphocytes 30, polymorphs 1), red blood-cells 1 per c mm , chloride 700 mg per 100 ml , sugar 95 mg per 100 ml No bacteria were seen on Gram and Ziehl-Nielsen staining

Diagnosis and treatment —The diagnosis was considered to be either acute encephalitis, possibly influenzal, or fulminating tuberculous meningitis The patient was seen by Dr W W Gooddy, who agreed and advised a further lumbar puncture the following day to see whether by then the C S F sugar and chloride levels had changed Repeat lumbar puncture on the following morning yielded C S F under a pressure of 300+ mm H_2O, containing protein 180 mg per 100, white blood-cells 66 per c mm (polymorphs 57%, lymphocytes 38%, monocytes 5%), red blood-cells 9 per c mm , chloride 725 mg per 100 ml , sugar 58 mg per 100 ml

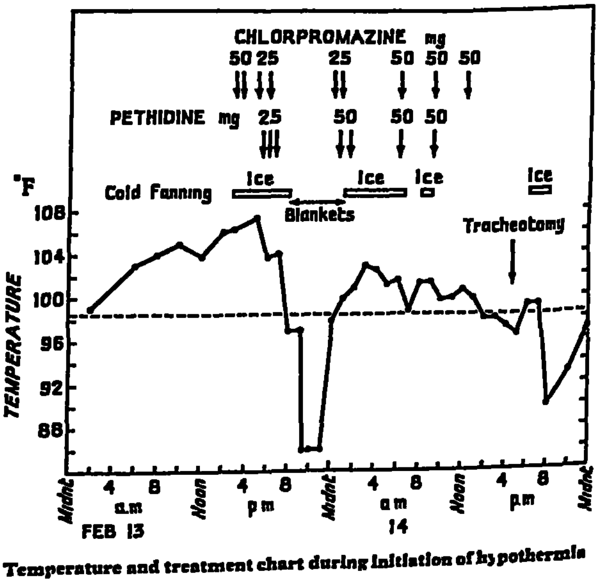
Acute encephalitis was diagnosed and treatment was directed to preventing complications until consciousness returned—particularly of the chest in view of the persistent cyanosis and shallow breathing An endotracheal tube was inserted to maintain a good airway A tracheotomy was performed the following afternoon by Mr B V McEvedy

At 2 A M that morning the patient's temperature was 99°F, at 6 A M 103°F, at 8 A M 104°F, at 10 A M 105°F, cold sponging and fanning were instituted At noon the temperature was still 105°F, by 2 P M it had risen to 106 2°F, and by 2 30 P M it was 106 4°F All temperatures were taken rectally

Induction of hypothermia —Since the continued rise of temperature seemed likely to prove fatal the decision was made to use hypothermia in an attempt to reduce the temperature to normal Chlorpromazine alone was given initially (since pethidine was contraindicated by the shallow breathing and cyanosis) and the trunk and limbs were covered with ice. Shivering was not entirely prevented by chlorpromazine, and in the first two hours the temperature did not fall, in fact it rose to 107 6°F at 5 30 P M During this period the patient's respiratory excursions improved greatly and his cyanosis lessened Pethidine was then administered intravenously, in conjunction with chlorpromazine this controlled the shivering and the temperature fell to 97°F by 8 P M The ice, ice water, and fans were removed and blankets placed on the patient Despite this his temperature continued to fall, and an hour later it had reached 86°F He was then warmed, but his temperature rose to 103°F With further cooling it fell to 90°F and then rose to 97°F It was then maintained at 96–98°F until consciousness was regained sixty-five hours after admission The amounts of drugs given and temperature chart are shown in the accompanying figure

Further treatment and progress —During the period of unconsciousness the water and electrolyte balance was maintained principally by means of 2 5% glucose in 0 45% saline solution administered initially through an intravenous needle, but later through a polyethylene catheter inserted in the femoral vein His urine volume was well maintained after an initial period of oliguria No cardiac arrhythmias were detected

After regaining consciousness the patient was very restless, requiring sedatives during the next four days to control his agitation His behaviour then returned to normal The tracheotomy tube was removed on Feb 20



Temperature and treatment chart during initiation of hypothermia

Physical examination a week after return of consciousness showed nystagmus to the left. Otherwise there was no abnormality which had not been noted four years previously He had a retrograde amnesia dating back to about six weeks before the onset of coma, this defect of memory still persisted two months later He is also forgetful of recent events and complains of lack of ability to concentrate

Electroencephalography a fortnight after admission showed generalised abnormalities with rhythms down to 4 C.P S in the frontal areas A further examination a month later showed the expected improvement with a stable dominant α rhythm

Complement-fixation tests performed by the Central Public Health Laboratory, Colindale, on blood specimens, taken on the second day of his illness and three weeks later, were negative for antibodies to influenza A and B, the adenoidal-pharyngeal-conjunctival (A P C) group of viruses, Q fever, psittacosis, and streptococcus M G

The patient was discharged on March 17

Discussion

This illness was probably sporadic encephalitis in a patient who had had an influenzal-like illness two days previously and not "influenzal encephalitis", since antibodies to the viruses of influenza A and B could not be detected in the serum during the acute phase

The principal purpose in inducing hypothermia was to avert a known fatal complication of encephalitis—namely, hyperpyrexia due to disturbance of the heat-regulating centre A second purpose was to reduce oxygen consumption in a patient with persistent cyanosis Both these aims were achieved The possibility of using hypothermia in the treatment of hyperpyrexia was mentioned by Gray (1957) No reference to its use in the hyperpyrexia of encephalitis has been found Rowbotham et al. (1957), however, employed hypothermia to reduce cerebral metabolism and prevent death from hyperpyrexia in a case of head injury with a rising temperature, it is also used in neurosurgical procedures

Shivering was not abolished in this case by chlorpromazine alone, possibly the dosage was insufficient No cooling occurred while the patient was shivering Respiratory rate and depth were, however, greatly improved either by the chlorpromazine or by the stimulus of ice on the skin The addition of pethidine controlled the shivering, and the rectal temperature then fell very rapidly to 86°F (30°C) as the result of skin cooling by ice water During rewarming the rectal temperature rose to 102°F—not the 96–98°F aimed at The difficulty of controlling the cooling and warming of this patient emphasises the disadvantages of the technique of achieving hypothermia by skin cooling This difficulty was pointed out by Khalil and Mac Keith (1954), who advocated the use of an intragastric balloon irrigated with ice water—a method which proved satisfactory in rabbits and in a boy of 16 Khalil (1958) has reported the successful use of this method in the removal of intracranial tumours in two cases

The reduction of cerebral metabolism is greatest with reduction in temperature to 82°F, below that temperature further cooling results in little decrease of metabolic rate Stone et al (1956) showed that shivering causes a pronounced increase in cerebral metabolism, underlining the importance of abolishing shivering in these cases

In the present case the cause of the shallow breathing on admission was not clear An endotracheal tube was inserted initially so that respiration could be assisted if necessary Some difficulty was experienced in removing secretions, and the trecheotomy might have been performed earlier with advantage Efficient physiotherapy throughout the period of coma and the following days, together with penicillin, averted aspiration pneumonia

We thank Dr W Brooks and Dr P J Verrill for advice with regard to hypothermia, and Sister B Sowden and the nursing staff of ward 4

CHEST PHYSIOTHERAPY
DURING INTERMITTENT POSITIVE-PRESSURE RESPIRATION

LIONEL H OPIE

RESEARCH ASSISTANT *

J M K SPALDING
D M Oxon, M R C.P
NEUROLOGIST

From the Respiration Unit, Department of Neurology, United Oxford Hospitals

THE introduction of intermittent positive-pressure respiration (I P P R) by Lassen (1953) was an important advance in the treatment of respiratory paralysis This method was first used in treating cases of poliomyelitis, but its scope has since been extended to include treatment of cases of acute polyneuritis, tetanus, barbiturate poisoning, myasthenia gravis, bronchitis with emphysema, and other conditions When artificial respiration is required for patients with paralysis of the respiratory muscles, the patient is normally too weak to cough sufficiently to clear the bronchial tree of secretions so that there is a special liability to pulmonary complications

In the prophylaxis and treatment of these complications, which may well determine the final outcome, physiotherapy to the chest is of prime importance (Lassen 1953, Smith et al 1954) It is normally given in the form of "vibration" to the chest wall followed by powerful compression of the chest, the whole manœuvre occupying less than one second and being repeated with each breath The patient is postured to drain the part of the lung receiving treatment We consider here the mechanisms by which this physiotherapy is effective

Modern electronic manometers have played an important part in the elucidation of mechanical properties of the chest, and important contributions have thus been made in recent years to knowledge of both normal and abnormal lungs and thoracic cage In the present investigation manometers of this type have been used to measure the pressure changes in the thorax during artificial respiration with and without chest physiotherapy, and this has thrown light on the mechanism by which chest physiotherapy produces its effect

Methods

Œsophageal pressure was measured by an air-filled polyethylene tube 1 5 mm bore, enclosed over the terminal 18 cm by a latex balloon which tolerated the introduction of 2 ml air when lax and free before any pressure change The part of the tube inside the balloon had a hole in its wall every 2 cm All pressure changes were measured with a capacitance manometer and recorded on a direct writing recorder Air flow was measured by a modified Lilly (1950) pneumotachograph

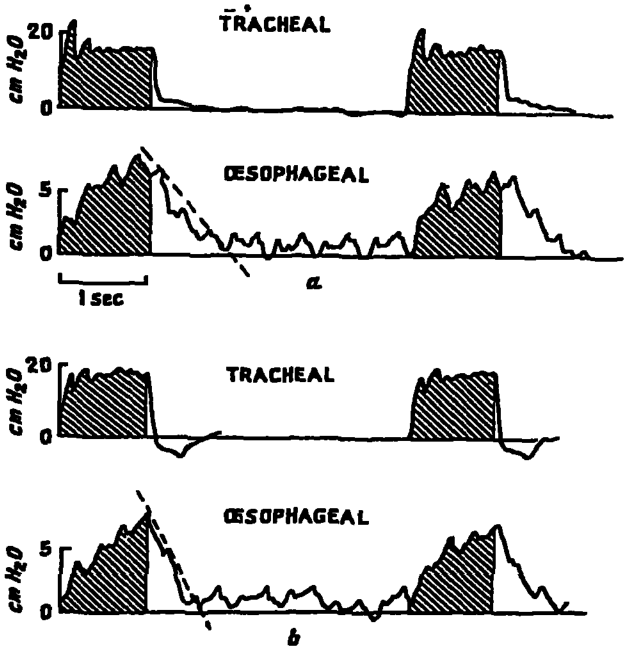

Fig 1—Pressure in trachea and œsophagus during I P P R Inspiratory period is hatched In fig 1b expiration is expedited by short negative-pressure phase, as is shown by slope of dotted line

In order to determine the air flow in centimetres per second the coronal diameter of the trachea was measured on a radiograph taken in the expiratory position The diameter of the tracheotomy tube was known, and its apparent diameter was measured on the radiograph This enabled a correction to be made to the radiographic diameter of the trachea to provide the real diameter The sagittal diameter was taken to be five-sixths of the coronal diameter (Engel 1947), and the cross-sectional area of the trachea was derived from these figures Six patients were receiving I P P R from a 'Radcliffe positive-negative-pressure respiration pump' (Russell et al 1956), two were on pumps of comparable design but with no negative-pressure phase Every patient had a cuffed rubber tracheotomy tube (Spalding and Smith 1956) The cuff was inflated sufficiently to provide an airtight fit in the trachea Subatmospheric pressure is referred to as negative pressure

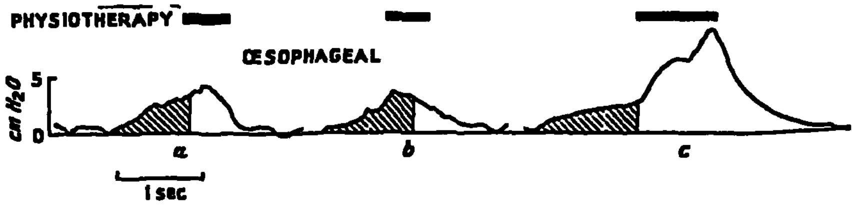

Fig 3—Effect of less usual types of physiotherapy on œsophageal pressure (a) with hands on anterior and posterior aspects of chest, (b) with pressure to abdomen only, (c) with synchronous pressure to abdomen and chest

Results

During inspiration by I P P R the pressure in the trachea is raised and air enters the lungs As this occurs and the lungs inflate, the pressure in the œsophagus rises (fig 1a) During expiration the tracheal and œsophageal pressures fall rather steeply provided a satisfactorily free passage is available for the expired air Expiration may, however, be expedited by a negative pressure in the trachea (fig 1b), and, as this is the pressure pattern we normally use clinically, it has been used during this investigation The œsophageal pressure is modified during physiotherapy, and fig 2 shows œsophageal pressures with physiotherapy occurring during inspiration (fig 2a), early in expiration (fig 2b), and in the middle of the expiratory period (fig 2c) Fig 2b and c were taken during unusually vigorous physiotherapy, and in normal treatment the œsophageal pressure is raised to a peak of only about 4 cm water The timing of the compression varied from one physiotherapist to another All started at the beginning of expiration The majority gave a preliminary period of "vibration", followed by forceful compression in the middle of the expiratory period *(fig 2c), when they could feel that the chest had* virtually returned to the resting position Others omitted the vibration and compressed during the period of rapid initial deflation in early expiration (fig 2b)

Physiotherapy is usually given with the hands placed close together over the part of the lungs to be treated Fig 3a shows the effect of holding the hands on the posterior and anterior aspects of the chest, another method commonly used Fig 3b shows the effect of pressure on the abdomen only, and Fig 3c of synchronous pressure on the chest and abdomen This last produces a very pronounced rise in œsophageal pressure, but as it requires two operators it is inconvenient in practice Fig 4 shows the effect on the œsophageal pressure of chest compression of the normal duration 0 5 sec, and of a longer period—1 25 sec

The rate of air-flow in and out of the lungs is related to the œsophagotracheal pressure, since the œsophageal pressure is closely related to the intra-pleural pressure (Dornhorst and Leathart 1952, Fry et al 1952) Therefore the rise in œsophageal pressure during physiotherapy (fig 2b) accelerates expiration A greater and more prolonged alteration in this pressure gradient can, however, be produced by increasing the negative pressure to the trachea during expiration Fig 5 shows the maximal negative pressure produced in

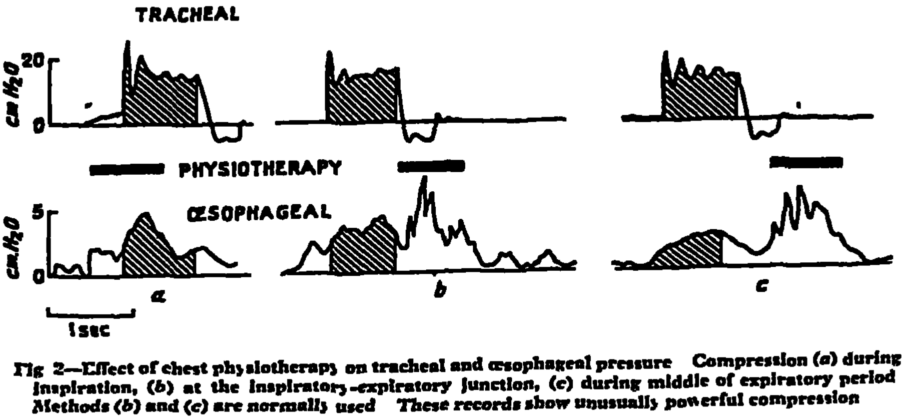

Fig 2—Effect of chest physiotherapy on tracheal and œsophageal pressure Compression (a) during inspiration, (b) at the inspiratory-expiratory junction, (c) during middle of expiratory period Methods (b) and (c) are normally used These records show unusually powerful compression

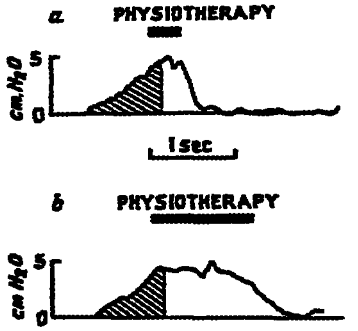

Fig 4—Effect of duration of physiotherapy on œsophageal pressure (a) brief compression (less than 0·5 sec.), (b) prolonged compression (1·25 sec.)

the trachea and œsophagus by the Radcliffe positive-negative-pressure respiration pump One of the features of this respiration pump is that negative pressure is produced by gravity and therefore comes into operation without delay It produces a negative pressure in the trachea of about 10 cm water so that the œsophagotracheal pressure gradient is greater than that produced by physiotherapy Moreover, the œsophageal pressure is still raised when this negative pressure is applied to the trachea, so that the pressure gradient is further increased (fig 5) As physiotherapy usually causes a pressure difference of about 4 cm. water, the negative pressure produced by the pump results in a much greater œsophagotracheal pressure difference.

These findings were supported by studies of the air-flow through the tracheotomy tube. The expiratory flow was expedited by negative pressure in the trachea, which increases the flow considerably more than does chest compression given at the inspiratory-expiratory junction. Application of compression later in the expiratory period (fig 2c) caused very slight alteration in air-flow Maximum air-flow recorded with the positive-negative-pressure respiration pump was less than 2 litres per sec, corresponding to a speed of 16 m per sec (51 ft. per sec., 36 miles per hour) compared with speeds close to that of sound in the trachea during normal coughing (Ross et al 1955)

Discussion

Physiotherapy to the chest is an effective method of removing secretions from the lungs There are two principal mechanisms by which it may act

1 By raising the intrathoracic pressure as a whole it causes air to be rapidly expelled from the lungs, and possibly the blast of air thus created carries secretions along, as in the normal cough sputum is carried from the trachea to the exterior

2 By local compression of the consolidated lung the retained material may be squeezed out along the bronchus, as tooth-paste is squeezed out of its tube This has been observed during bronchoscopy (A. C. Smith, personal communication)

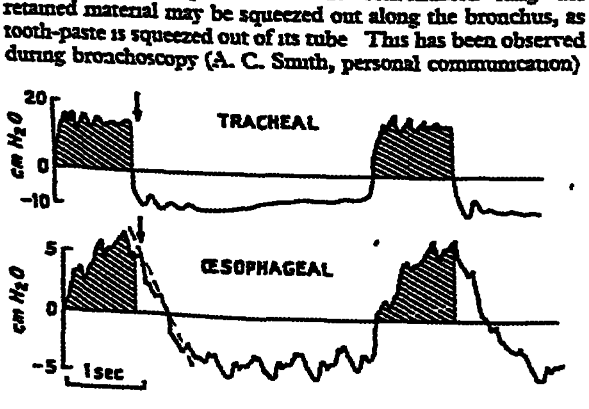

Fig 5—Tracheal and œsophageal pressures with negative pressure of 7-10 cm. water in trachea throughout expiration. At arrow œsophagotracheal pressure gradient is about 13 cm. water

For a given part of the respiratory cycle the air-flow is related to the pressure difference between the œsophagus and trachea, and the records (figs 2 and 5) show that a greater pressure difference and greater air-flow can be produced by the respiration pump than by the physiotherapist Clinical experience indicates, however, that a negative-pressure phase from a respiration pump is a totally inadequate substitute for chest physiotherapy The increased expiratory flow with physiotherapy is not even capable of expelling loose secretions through the tracheostome, and endotracheal suction through a soft rubber catheter is necessary to remove secretions when they have reached the larger bronchi Moreover, physiotherapy during the middle of the expiratory period (fig 2c) is as effective as in early expiration (fig 2b), although the air-flow is very much less It therefore seems probable that the vital part in physiotherapy of the chest is the direct squeezing of that part of the lung beneath the physiotherapist's hands and that this pushes the secretions out into the main bronchi Machines have been designed which are intended to clear secretions from the chest of a paralysed patient, their principle being to inflate the lungs to a considerable pressure and suddenly apply negative pressure to the trachea This produces a considerable outflow of air in a short time, though probably the flow rate is much slower than in normal coughing (Whittenberger 1957), but it does not simulate the squeezing of a consolidated lobe that appears to be so valuable in chest physiotherapy This may account in part for the fact that these "cough-machines" have not been more widely adopted

During normal respiration the intrathoracic pressure is subatmospheric during inspiration, and this assists the return of venous blood to the heart During artificial respiration by I.P.P.R. (and similar considerations apply to the tank respirator) the pressure in the chest is raised during inspiration, impeding return of blood to the heart (Werkö 1947), and the maintenance of cardiac output may depend on compensatory mechanisms Physiotherapy to the chest further increases the intrathoracic pressure In our experience, however, this hardly ever justifies the omission of chest physiotherapy even in a patient who is very ill and whose compensatory mechanisms are suspect. In such a patient we sometimes give physiotherapy in the horizontal and head-down positions, but omit the head-up position normally used for treating the upper lobes Clinical experience has shown that each period of chest compression need only be brief, up to about 0·75 sec. (fig 2b and c, fig 4a), for prolonged compression appears to be no more effective For the same peak œsophageal pressure, periods of compression of 0·4 sec. and 1·25 sec. (fig 4) result in an increase in mean œsophageal pressure of 50% and 200% respectively The shorter period therefore places a smaller strain on the circulation.

Summary

Physiotherapy to the chest is an effective method of removing secretions from the lungs of patients with respiratory paralysis

The life-saving benefits of physiotherapy are due to direct squeezing of the part of the lung beneath the physiotherapist's hands, not to a general increase in the rate of expiratory flow

We wish to thank Dr W Ritchie Russell and Dr A Crampton Smith for their advice and assistance

FAMILIAL OUTBREAK OF ACUTE GLOMERULONEPHRITIS DUE TO GRIFFITH TYPE-1 STREPTOCOCCUS

H J GOLDSMITH
M D Lond , M R C P
SENIOR MEDICAL REGISTRAR

M A COWAN
M B Sheff
SENIOR HOUSE-OFFICER

E GOODER
B Sc Leeds
NON-MEDICAL BACTERIOLOGIST

SHEFFIELD ROYAL INFIRMARY

THE opportunity of investigating, at an early stage, the bacteriology of familial outbreaks of acute glomerulonephritis does not often arise

We have been unable to trace any report of a family or community outbreak in which infection with the β-hæmolytic streptococcus, Lancefield group A, Griffith type 1, resulted in acute nephritis in as many as four members out of ten affected

In the familial outbreak of acute nephritis we describe, such a "nephritogenic" action has been demonstrated for a type-1 streptococcus

History of Outbreak

The family Q consists of father, aged 40, mother aged 38, and nine children aged 17–1½ years The family lives in a semidetached house with 6 rooms (3 bedrooms) in a large village on the outskirts of Sheffield None of the family had suffered from scarlet fever, rheumatic fever, or frequent attacks of acute tonsillitis and none had undergone tonsillectomy

The main clinical and bacteriological features are summarised in the accompanying table In the first week of February, 1958, Joan Q contracted severe acute tonsillitis Three to four weeks later her sisters Jane and Mary developed severe attacks of the same illness The following week John, Martha, Francis, and Rose Q developed mild infections of the upper respiratory tract within a few days of each other Kenneth Q, the youngest, fell ill with cervical adenitis and acute otitis media after the four preceding children had recovered Both parents developed sore throats a week after Kenneth had fallen ill, and the mother subsequently had monoarthritis The only member of the family not to suffer some clinical illness up to this point was the eldest son, Harold Only Kenneth received systemic penicillin Some of the others were treated with oral penicillin

Case 1 —Joan Q was admitted to the Sheffield Royal Infirmary on March 3, 1958, with a history of dyspnœa and passage of dark urine for the past week, and of generalised œdema for forty-eight hours Anasarca and pulmonary congestion were confirmed, the blood-pressure was raised, and the urine contained albumin, red blood-cells and casts A throat swab prior to penicillin therapy grew commensals only The patient was treated by bed rest, restriction of protein, fluid, and salt intake, and systemic penicillin for fourteen days, followed by oral phenoxymethylpenicillin until her discharge on April 4 She was then symptom-free and the blood-pressure had returned to normal, but the urine still contained some albumin, red blood-cells, and occasional hyaline casts A week after returning home the patient had recurrence of acute tonsillitis, which was treated with oral penicillin When her condition was reviewed on April 18 a β-hæmolytic streptococcus was grown from a nasal swab

Case 2 —Her mother informed us that Joan's sister, Jane, had been admitted to the Sheffield Royal Hospital on April 5 with severe acute nephritis A throat swab taken after three days' penicillin therapy grew only mouth commensals Jane was treated with systemic penicillin for twenty-three days Further throat and nasal swabs on April 17 again failed to grow pathogens

Case 3 —The family doctor sent up a third daughter, Mary, who had developed hæmaturia and facial swelling a week previously A throat swab after admission (April 18) grew a β-hæmolytic streptococcus She received the same treatment for acute nephritis as case 1 and was discharged to a convalescent home on May 8

As soon as it was realised (April 18) that multiple cases of acute nephritis had occurred, the whole family was asked to attend (April 19) for further investigation The only abnormalities discovered were unilateral conjunctivitis in the mother (present for a month, complicating long-

standing nasolacrimal duct obstruction), an infected nose in Martha, and cervical adenitis with a discharging middle ear in Kenneth. The blood-pressure was measured in all except the two youngest children and was found to be normal. Non-catheter specimens of urine were normal in each case except that of Joan, who had been recently treated for acute nephritis and whose urine still contained some albumin and red-blood cells, and of Martha, whose urine contained a moderate amount of albumin, an excess of red blood-cells, occasional cellular casts, and leucocytes No other clinical evidence of acute nephritis was obtained in this girl and the urinary abnormality was thought to represent mild acute nephritis Throat and nasal swabs were taken from all those attending In addition the mother's conjunctival and Kenneth's aural discharges were cultured β-hæmolytic streptococci, Lancefield group A, were isolated from one or more sites in all those examined, except Harold.

On May 1 the family was visited at home We learned that Harold had developed pains in both ankles during the previous week, and was receiving physiotherapy at a clinic. On this occasion his throat swab grew a β-hæmolytic streptococcus, later found to be of Lancefield group A, Griffith type 1 His erythrocyte-sedimentation rate (E S R.) was 44 mm in the 1st hour (Westergren) and his anti-streptolysin titre was 600 Further throat and nasal swabs were taken in six of the others β-hæmolytic streptococci group A were again isolated from each except Kenneth The first β-hæmolytic streptococcus isolated from each subject was later typed in the Streptococcal Reference Laboratory, Colindale, through the courtesy of Dr R. E O Williams, and found to be of Griffith type 1, except the streptococcus from Mrs Q's conjunctival sac, which belonged to type 2 Blood was taken from cases 1–3 and their mother (May 30), and the sera were tested for type-specific antibodies In each case antibody against type-1 streptococcus was demonstrated, and there was a suggestion that the antibody was more active for the homologous strain than for a stock type-1 strain There was only slight activity with the sera from cases 1–3 against some type-12 strains—not strong enough to suggest that the nephritis was really due to an inapparent type-12 infection.

Discussion

We feel that this familial outbreak of upper-respiratory infection was caused by a type-1 streptococcus for the following reasons.

1 The organism was recovered from ten of the eleven members of the family within two to nine weeks of the individual initial throat infections

2 No other types of β-hæmolytic streptococci were isolated from a total of thirty-nine swabs with one exception that from Mrs Q's conjunctiva grew a type-2 streptococcus, but she also carried a type-1 in her nose and throat. Harold Q was the only member of the family whose swab failed to grow any streptococci on April 19, and he was the only one who had not by then contracted an infection of the upper respiratory tract. A few days before the second swabbing on May 1, which grew type 1 streptococcus, he contracted polyarthritis

3 Blood taken from cases 1–3 and from their mother (May 30) contained antibody to type-1 streptococcus

It has been appreciated for some years that, with few exceptions, the incidence of rheumatic fever following Lancefield group-A streptococcal infection is fairly low and that the attacks are not associated with any specific type (Siegel et al 1955) In contrast to this, the incidence of acute nephritis, following streptococcal infection varies considerably in different streptococcal outbreaks In recent years the bacteriology of community outbreaks of acute nephritis has been studied by typing the streptococci isolated from the upper respiratory tract. These studies have shown that in cases of acute nephritis certain types of streptococci are much more commonly isolated than other types Thus, types 4, 12, and 25 have been incriminated in various parts of the world. A hitherto undescribed type of streptococcus—Red Lake—has been added to the known "nephritogenic" types (Updyke et al 1955) Infection with other types, including type 1, have been associated only sporadically with acute nephritis In Great Britain Wilmers et al 1954 found that of 31 cases of acute glomerulonephritis, treated in various London and provincial hospitals, 28 grew type-12 streptococcus, while the remaining 3 grew types 1, 2, and 3 respectively In a concurrent investigation in which β-hæmolytic group-A streptococci from 1380 patients were typed, type 12 occurred in 8 2% and type 1 in 10%. They concluded that in Great Britain as in the United States acute glomerulonephritis was closely related to infection with type-12 streptococcus From their figures no such relationship is discernible for type-1 streptococcus in 1953

In a large outbreak of streptococcal illness in Wyoming type-1 streptococcus was isolated from 196 patients, but no cases of acute nephritis developed amongst these (Rammelkamp and Weaver 1953)

The Q family outbreak appears to be the first reported in which a high incidence of acute nephritis following type-1 streptococcal infection has been demonstrated Of the ten affected members of the family three contracted clinical acute nephritis, and a fourth had the urinary changes of acute nephritis without displaying symptoms This type of renal reaction to streptococcal infection has been described after scarlatina (Harries and Mitman 1947) It is of interest that two of the infected people contracted rheumatic arthritis

It seems likely that the high incidence of acute nephritis in this family following infection with type-1 streptococcus was at least partly due to a "nephritogenic" variant of type 1 This is suggested by the fact that the sera of the patients showed a more powerful bactericidal power against the strain of type-1 streptococcus, involved in this outbreak, than against a stock "non-nephritis" type-1 streptococcus

Summary

Four cases of acute glomerulonephritis were detected in one family, following infections of the upper respiratory tract with β-hæmolytic streptococcus group A, type 1

A distinct "nephritogenic" action has not previously been ascribed to the type-1 streptococcus

We thank Dr E W Skipper for permission to publish, Prof C H Stuart-Harris and Dr D Verel for access to the notes of case 2, and the family practitioner, Dr P W O Brien, for helpful information The streptococcal grouping was carried out in the departments of Dr J Colquhoun and Dr E H Gillespie, to whom we are grateful for criticism and advice We also thank Dr R E O Williams who kindly typed the organisms, demonstrated type-specific antibodies, and discussed the outbreak with us

Reviews of Books

Scottish Social Welfare, 1864–1914

THOMAS FERGUSON, C B E , M D , F R C P E , professor of public health, University of Glasgow Edinburgh E & S Livingstone 1958 Pp 610 42s

THIS vast storehouse of information carries on the story begun in *The Dawn of Scottish Social Welfare,* published in 1948 If the later period differs from the earlier days in that its contrasts are less spectacular, the change which has overtaken social affairs since 1914 is still remarkable and no less remarkable is the change which has come over the public attitude to social problems Long and interesting chapters deal with general environment, housing, food, the relief of destitution, infectious diseases, the care of the sick, and the welfare of mothers and young people Particularly interesting are the changes in such varied communities as the city of Glasgow and the isolated crofters in distant islands In both places the housing problem was formidable and utterly different

To begin with, the education of the adult population of remote parts, especially in the Hebrides, did not improve rapidly, so far at least as capacity to sign marriage registers was concerned In Scotland as a whole, 10% of men and 20% of women signed by a mark in 1862 and 1872, and 7% and 14% respectively in 1881 Judged by this standard, much the most backward counties were Inverness and Ross and Cromarty, in Ross and Cromarty, 34% of men and 49% of women signed by the mark in 1862, 26% and 49% in 1872, and 24% and 47% in 1881 But the report of the Crofters' Commission in 1884 was able to claim that, while the educational level of adults in these counties was much below the Scottish average, the number of children being educated in that year was greater in proportion to population than in any other county except Caithness By 1910 the figures had fallen to 5%

Sekretionsstudien am Pankreas

Experimentelle und anatomische Pathologie DR VOLKER BECKER, Pathologisches Institut der Universitat Kiel Stuttgart Thieme 1957 Pp 119 DM 29 50

Dr Becker's monograph is a thorough attempt to correlate the histological features of the excretory tissue of the pancreas with the functional states produced in animal experiments Thus, the static picture of a histological section is identified with a definite stage in the disease process The results of ethionine-inhibited protein synthesis, of parasympathetic, splanchnic, and secretin stimulation, and of duct ligation, are described in laboratory animals killed at different intervals after the experiment began And work has also been concerned with the size and shape of secretory cells, distribution of zymogen granules, basal basophilia (as an expression of ribonucleic-acid content), size of nuclei, and distribution of chromatin and of nucleoli

Findings in human necropsy material are then described and interpreted on the basis of animal experiments 350 cases were studied, in 50 of which the necropsy was performed less than two hours after death Dyschylia, a secretion of abnormal fluid, and parachylia, an abnormal pathway of secretion, are terms used and discussed Reasons are examined for the belief that the dual secretions—parasympathetic-stimulated, rich in enzymes (proteochylia), and secretin-stimulated, alkali-rich and aqueous (hydrochylia)—have their morphological equivalent in an anatomical partition, the first being secreted by cells of the acinus, the second by cells of the isthmus

Some of Dr Becker's claims may be contested Thus, the increase in chlorides in the saliva in fibrocystic disease of the pancreas is explained by deficient dilution via duct cells, but the function of duct epithelium is water resorption against an osmotic gradient The strong reduction of tetrazolium salts by the duct epithelium, so conspicuous in the parotid and submaxillary glands, is wrongly attributed to pancreatic ducts also The role of postmortem autolysis is probably underestimated

Anyone interested in pancreatic disease will find the book useful and stimulating, and there is an exhaustive list of references

The Clinical Physiology of Physical Fitness and Rehabilitation

ERNEST JOKL, M D , professor and medical director, Rehabilitation Center, University of Kentucky Springfield, Ill Charles C Thomas Oxford Blackwell Scientific Publications 1958 Pp 194 63s

THIS book is based on an essay for which the author was awarded the Buckston Browne prize and medal of the Harveian Society of London He suggests that, though medicine has made great advances in the past fifty years, these have been accomplished principally by utilising laboratory and experimental methods, to the detriment of the art of clinical observation In the present work he seeks to redress the balance, pointing out that the worker in physical medicine and rehabilitation is ideally placed to develop new clinical techniques

One obstacle is that the scientific basis of rehabilitation is still only vaguely defined Indeed, the realisation that rest alone will not always suffice for the optimum recovery of the body from a disease process, is comparatively recent Dr Jokl elaborates the thesis of Julius Cohnheim and William H Welch that "the healing power of nature is frequently incomplete and imperfect" by describing instances in which dissatisfaction at the results yielded by this natural power, operating alone, led to high and imaginative standards in rehabilitation Such standards have sometimes resulted in almost incredible accomplishments (for example, the world record in hammer-throwing was, in 1956, held by a man whose left arm was almost totally paralysed)

This book can profitably be examined from several different angles It is a monograph in physiological research, reporting original work on the prognostic significance of the ballistocardiogram It is a study of the recent history of physiology, embodying a series of short, but attractively illustrated, biographies of such figures as Sir Charles Bell, Hughlings Jackson, and Amand Duchenne Finally, the case-histories it embodies constitute intriguing and stimulating examples of the remarkable standards of recovery which are, on occasion, attainable even by the seriously handicapped

An Atlas Concerning Morphological Aspects of Visceral Nerve Endings

Contribution to the Study of the Problem of Interoceptors Prof DR I NICULESCU, M D , corresponding member of the Rumanian Academy of Sciences Bucharest Editura Medicala 1958 Pp 455

THIS work appeared some months after the death of its distinguished author The text amounts to only 30 pages, but it is repeated in several languages, including English It includes a useful section on the intraneuraxial pathways of the interoceptors and proprioceptors, and a short account of the cortical representation of vegetative functions The many drawings illustrating nerve-endings in various laboratory animals are mostly in two or three colours and are very clear Methylene-blue and carmine appears to be his method of choice for fresh impregnation, but use is also made of various standard silver techniques One illustration shows the autonomic microganglia of the subserous layer of the human fœtal bladder, which is so rich in synaptic structures

Eden and Holland's Manual of Obstetrics (11th ed London J & A Churchill 1957 Pp 751 63s)—In the latest edition of this classic Mr Alan Brews provides a comprehensive and easily read account of current obstetric practice It is profusely illustrated with excellent diagrams and plates There is little emphasis on manipulative and operative obstetrics, which is proper in a book intended primarily for the undergraduate In spite of claims to the contrary the M R C O G candidate will be obliged to read more widely obstetric anæsthesia is only briefly considered, Kielland forceps get half a page, pudendal-nerve block is just mentioned, Lovset's manœuvre is not described, and the account of the management of breech delivery is not fully up to date Nevertheless, the book can be thoroughly recommended to the undergraduate, and the general practitioner will find in it a sound answer to every unusual obstetric problem

THE LANCET

LONDON 27 SEPTEMBER 1958

Resources for Research

THOSE who visit American medical schools are impressed by the amount of money at their disposal for medical research. Last year the grant from Federal funds alone was $186 million; industry contributed $90 million, charitable foundations earmarked $35 million for specific projects, and further substantial sums came from local collections (e.g., "Heart Sunday") and sums allotted by individual States to their universities. The municipality of New York has just set up its own Health Research Council with an initial appropriation of $600,000 and a possible eventual budget of $8 million a year (see p. 702). Congress has now been told by a special committee that it is not putting enough money into medical research and that $1000 million annually should be spent by 1970.[1] Yet already Congress is putting into research twenty times the budget of our Medical Research Council. This vast endeavour is exemplified in the National Institutes of Health at Bethesda with 6000 medical and ancillary staff. In the U.S.A. all avenues into medical research are wide open, and there are splendid facilities even at the student stage. Hospital consultant staffs are far larger than ours, and at every grade each member is expected to contribute actively to the development of ideas in medicine. Dr. SMYTHIES' article on p. 689 of this issue graphically underlines the prominence of research in American thought. In our more strictly selective system, necessitated by relative poverty of money and facilities, many American investigators would hardly have had a chance. By full deployment of their talent, and by the efforts of great numbers, an immensely rich soil is being developed from which new research ideas can be harvested.

When new scientific approaches originate in this country they may be elaborated all too slowly by "one man and a boy" working in cramped space with makeshift equipment, whereas in the United States large teams at once get to work on every promising idea. Consequently we have depended on the United States for the development of new antibiotics, and to the United States, too, must go full credit for most of the progress in protection against poliomyelitis. These are advances well known to the man in the street, but far more important is the ferment of new biological ideas from which other discoveries will spring. Fundamental biological and physiological science in the U.S.A. is closely integrated with clinical research, and extensive laboratories are available not only to the basic medical scientists but also to clinicians for studying problems arising out of human disease. By contrast, medical research in this country is undergoing relative attrition despite an expanding economy. In the universities new building for medical and biological sciences is much more restricted than that for physical and technological subjects. There is no surgical animal research laboratory in any English university—though one is now nearing completion. There have been no new teaching hospitals in this country since the 1939–45 war, so even the application of the new methods developed here or elsewhere is frustrated or difficult. Careers in basic medical science have become unattractive in salary and prospects compared to the glamour of consultant medicine—once achieved. The young clinical trainee who engages in research is often terrified that he will thereby become labelled a "laboratory man" (derogatory only in this country) or too specialised for the next vacancy in a provincial hospital. The real gravity of our situation is underlined by the fact that some of our research directors and medical professors, as well as promising younger investigators, are leaving this country to work on the other side of the Atlantic, where they find that, in their laboratory and investigative work, they are given encouragement, lavish support, and almost unlimited opportunity. This is happening even though adaptation to the American way of life may be none too easy for the expatriate of mature years.

We may claim that, because of the very restriction of opportunities, there is a more concentrated selection of ability in British medicine—that in American medical research, as in the American economy, there is much waste. Our professional leaders are in fact very highly selected, but if the scientific training of our young men continues to be discouraged our leaders will be selected from a dwindling field of applicants. Already our medical faculties often find great difficulty in filling their professorial chairs. We justly pride ourselves that under the N.H.S. there are more specialists than ever before, but we should not pretend that this growth in specialist services will by itself keep British medicine in the forefront. We cannot maintain our standards without the vigorous pursuit of research in our medical schools, for even good routine will decline without the stimulus of critical thought engendered by investigative work. Scholarship alone—meaning the study of other people's thoughts—can never keep a profession alive. It failed in the Middle Ages and it would fail again now.

With our smaller population and national income we naturally cannot spend as much money on research as the United States. But we could with advantage spend more than we do, and we should make sure that our resources are used with imagination. Poverty need not make us too despondent, or proud, to learn from the American system such useful lessons as the encouragement of research among all branches of the profession, including students. The clinical prizes offered by some regional hospital boards and the more ambitious studies being made by the College of General Practitioners recognise this need. Again, though we cannot compete with the generosity of American industry and trusts, we could perhaps foster a new age of patronage. Lord Nuffield has already shown us the way, two of the royal colleges have lately received princely gifts for research, and the Mental Health Research Fund, which supports some investigations into the problems Dr SMYTHIES mentions, offers an opportunity for ordinary citizens to make small contributions

---

[1] *N.Y. Times*, July 14, 1958.

Our Commonwealth links no longer depend on the strength of our military force, but on our scientific, cultural, and commercial leadership (Many of us can remember the uplift to the national pride and prestige of Canada which followed the discovery of insulin) Supported by the basic disciplines of physiology, biochemistry, and microbiology, which in turn utilise techniques of physics and chemistry, medical science is a part of general science Progress in one science inevitably impinges on all associated branches Uneven progress of science is impossible, and thus the present policy of preferential development of the physical sciences seems to be utterly faulty In the U S S R, where the academician holds the highest place in society, there are signs of an intensified application of basic sciences to medical problems In this country we have no lack of talent, but without more financial encouragement, more laboratories, and more facilities for research, we shall lose our best workers, and gradually the standards of medicine even at a practical level will decline

First Responses to Local Infection

How primary bacterial infections may in nature be limited to the site in which the organisms first lodge and multiply is still unknown Although hyperæmia, heat, swelling, suppuration, and healing follow primary infections and are known to be due in sequence to to dilatation of blood-vessels, increased blood-flow, œdema, and diapedesis of leucocytes, then regression of these dynamic events, and finally scarring, their relation in time to the death and restricted spread of bacteria is still open to question Direct visual observations of these events in response to injury in transparent tissues have usually been made using chemical or physical agents with limited action whose extent depends on the dose Yet even with these it cannot be judged when the stimulus to the response ends and the consequences of the response begin The problem of these time-sequences is increased with living micro-organisms through their own capacity to multiply and produce injurious substances which in their turn damage the tissues chemically Thus an infection with living bacteria will be limited and localised only if the bacteria are prevented from escaping and are killed on the spot On the spot or nearby are phagocytes and their potential progenitors which can kill bacteria, and destructive antibody may be generated locally and possibly rapidly In vascular tissues both cellular and humoral antagonists are brought to the site by the blood-stream Though the possibility of local destruction of bacteria in non-vascular regions has long been known, it has usually been assumed that blood-borne phagocytes and non-specific immune substances are decisive in limiting infection in vascular tissues Localisation has been attributed by some to thrombotic plugs in efferent blood and lymphatic vessels The decisive factors limiting infection will be those which first kill infecting bacteria Thus the time after infection at which these are all dead or so greatly decreased as to be ineffective must first be known before the manner of their death can be determined A decision to investigate local events in the first five hours after the infections which were known to remain localised was arrived at by BURKE and MILES [1] on the basis of much previous experience of MILES and his coworkers [2-4] using enhancement of infectivity to judge the time when most of the bacteria were killed

Inflammatory lesions of a standard size were obtained consistently at twenty-four hours after injections of suspensions of known bacterial content To produce a final lesion of the same size different numbers of bacterial cells were required for different micro-organisms Experience showed that the size of the definitive lesion could be modified much by various enhancing agents When these were injected within three to four hours after primary infection the size of the twenty-four-hour lesion was increased The enhancing agents were adrenaline, general shock, and liquoid (an inhibitor of complement) The degree of enhancement was measured as increase in lesion size, and it could be interpreted as equivalent and proportional to an increase in the number of bacteria of the primary infection Enhancement occurred, however, only when attempted within three to four hours after primary infection From these observations it was concluded that after the first few hours the bacteria were either dead or so greatly diminished as to be incapable of responding by further damaging action to the favourable conditions afforded by enhancers The death-rate of bacteria was estimated at 50–99 9% in the first two hours of infection In a further paper MILES and MILES [5] have described a method of making bacterial counts in fresh tissues

Having found a decisive period within which both lesion size and localisation were determined for a given dose, BURKE and MILES [1] investigated the sequence of events in early infective inflammation Increased permeability (measured by dyeing with intravenous pontamine sky blue), increased stickiness of capillary endothelium (demonstrated with intravenous saccharated iron oxide), and tissue leucocytosis (estimated in stained sections) were used as criteria and measures of inflammatory response Capillary dilatation and œdema are not amenable to accurate measurement, though both are more directly representative of response Nine different infective agents, including one, *Streptococcus pyogenes*, isolated from a natural guineapig infection, were used to obtain lesions of a standard size of 10 mm in twenty-four hours In 6 of these the time-relations of vascular reactions were similar In the first two hours of the decisive period macroscopic signs of inflammation were scanty, they did not become obvious until the third or fourth hour, and they were not fully developed for several hours Capillary permeability, measured by the extent and depth of staining in the region around injected bacteria, increased transiently in the first half-hour, and subsequently there was a larger increase with a maximum at three to four hours In this second phase œdema and microscopically detectable leucocytosis increased Yet later, after the fifth hour, when induration and leucocytosis continued to increase, there was low permeability to the dye This observation causes Burke and Miles to suggest that the relation of vascular permeability phenomena to effective defence against local infection should be re-examined Of all the terms used, induration is left least defined If there is indeed "hardening", this is more than simple œdema In a previous publication Miles et al[4] stated that no fibrin could be demonstrated outside the central area which was destined to undergo coagulation necrosis Thus it seems that only the accumulation of phagocytes can account for this change in texture Great insight into the manner of dye diffusion along fibres and into œdema fluid has been provided by McMaster and Parsons[6] Their methods of observation may help to explain why dye no longer escapes while œdema fluid and leucocytes collect and the whole lesion becomes hardened During this early period there was no evidence of thrombosis of blood or lymphatic vessels

[1] Burke, J F Miles, A A *J Path Bact* 1958, 76 1
[2] Evans, D G, Miles, A A, Niven, J S F *Brit J exp Path* 1948, 29, 20
[3] Miles, A A, Niven, J S F *ibid* 1950, 31 73
[4] Miles, A A, Miles, E, Burke J *ibid* 1957, 38, 79
[5] Miles, A A, Miles, E *J Path Bact* 1958, 76, 21

To what extent can these findings be applied to natural infection? In the experimental infections the pathogenicity of the microorganisms used might be questioned, and Burke and Miles imply, and in one instance Miles and Miles[5] state, that with larger bacterial doses spreading and generalised infections occurred even in the absence of enhancers The particular example of systemic infection was seen with *Str pyogenes*[7,8] which had been isolated from a natural guineapig infection This essential piece of evidence removes two further objections to the realism of the experiments All the organisms, including the streptococci, had been frozen, dried, stored, and washed with distilled water before use. Several million were injected to represent an infecting dose, and they were introduced intradermally in a stabilising suspension which formed a small bleb about 1 mm in diameter How the suspension compares quantitatively with natural infection might be estimated Conditions inside a bleb are described, and further information on the situation may be gained from the revealing observations of S H Bensley[9]

The many observations now assembled indicate that the decisive period in which infection is limited precedes the classical early signs of acute inflammation in vascular tissues, and suggest that these early signs are responses to the aftermath of infection The versatility displayed in this series of publication should enable those taking part to proceed to the even more difficult task of detecting early unseen agents of bacterial destruction

Papa Virchow

As part of its autumn meeting in London, the Association of Clinical Pathologists is celebrating on Oct 3 the centenary of the publication of Virchow's *Die Cellularpathologie* with a symposium on the pathology of the cell, to be opened by Sir Roy Cameron with a paper briefly entitled "1858" It is an event well worth celebrating

Modern biology, after some centuries of irregular acceleration and many false starts, may fairly be claimed to have been launched on its tumultuous career with the publication in three successive years of three of the most seminal works of the whole scientific canon—Pasteur's *Memoire sur la fermentation appelée lactique* in 1857, *Die Cellularpathologie* in 1858, and *The Origin of Species* in 1859 It is easy to think of Virchow's work as important only as the well-head (with Morgagni's *De Sedibus*) of pathology, but it is a great deal more than that It established the cell as—after the body-as-a-whole—the prime unit of investigation, not only for medicine, but for biology in general Cells were of course not invented by Virchow The word is as old as Hooke's pioneer microscopic description of cork in 1665 The idea that living matter is characteristically divided into separate units, each with a nucleus, stemmed largely from the work twenty years earlier of Schleiden, Schwann, and Muller, and, in the descriptive sense at least, had already been greatly developed by Kolliker and Remak But Virchow added two major contributions to the "cell-theory" In the first place, he is responsible for one of the great biological generalisations—*Omnis cellula e cellule* By something more than coincidence, the core of all three of these near-contemporaneous works is their demonstration, on three very different planes, of the continuity of living matter Darwin destroyed separate creation, and showed that all species stem from a single family tree, Pasteur destroyed spontaneous generation, and showed that his "ferments", which were microorganisms, came from preexisting living matter, Virchow destroyed the idea that cells were a mere local crystallisation of protoplasm from an undifferentiated continuum, and showed that every cell resulted from the division of another cell In the second place Virchow established the "cell-theory" by showing that it had practical use The sharp realities of medical practice afford the sternest test and, if successful, the most brilliant vindication of any biological theory The cell-theory made it possible to understand the appearances presented by diseased tissues under the microscope, and added a new dimension to pathology (some day the electron-microscope will find its Virchow it is still in the Hooke stage) Though his techniques for the preparation of sections were primitive —paraffin embedding and most of our standard stains were at least a decade away—he launched the science of histopathology The enormous increase in accuracy of prognosis possible (in the case of tumours especially) by the use of microscopic methods based on Virchow's ideas supplied the best possible proof of their validity

[7] Miles, A A *in* Lectures on the Scientific Basis of Medicine, vol 3, p 235 London, 1955

[8] Dutton, A A C *Brit J exp Path* 1955, 36, 128

[9] Bensley, S H *Anat Rec* 1934, 60, 93

It is sad that most have heard of VIRCHOW as a diagnostic histopathologist only in the matter of the Emperor FREDERICK III, his misdiagnosis as benign of the biopsy taken by MORELL MACKENZIE from the Emperor's laryngeal carcinoma was one of the more distressing factors in that most distressing case Yet we may remember that even today this can be a difficult diagnosis, and that MACKENZIE, working with a mirror and no anæsthetic, may well have missed the real tumour Moreover, though it ruined MACKENZIE, the mistake was probably for the good of the patient, who would have been subjected otherwise to a laryngectomy, the mortality of which at the time was at least 75% In any case, before *Die Cellularpathologie* there would have been no biopsy VIRCHOW in fact made many mistakes Beside his brilliant elucidation of the cellular nature of leukæmia and of sarcoma there stands, for instance, a detailed account of the origin of carcinoma from the cells lining lymphatic channels But it is for his achievements rather than his mistakes that he is to be remembered And they were innumerable For fifty years he was the leading figure in German pathology, and this was a time when German pathology far outstripped that of the rest of the world He was in addition very many other things—anthropologist, archæologist, hygienist, politician His famous *Archiv*, founded in 1847 when he was 26, and still one of the world's leading medical journals, contains in its earlier volumes many contributions on subjects far removed from pathology

He remains even today the father figure of pathologists the world over He established the microscope as an essential tool of medical research and of medical practice He established pathology as an independent discipline, occupying the vantage point of a middle ground between the ivory tower of pure science and the clinical hurly-burly of pure application If today the average pathologist seems to have rather diverse interests, concerning himself with the blood-groups of the Aztecs one month and the hospital drains the next, he—and with him the whole profession and its patients—owes more than he generally realises to the example of Papa VIRCHOW

Annotations

LAYMAN'S AID

FOR eighty years the Order of St John of Jerusalem, through its Ambulance Association, has produced manuals for the instruction of the layman in the immediate management of injuries and sudden illness For almost as long the St Andrew's Ambulance Association and the British Red Cross Society have had similar textbooks This year their common aims and practices have had their obvious consummation in the production of a joint manual, simply titled *First Aid* [1] Nearly all accidents and sudden illnesses are seen and treated first by a layman, and people keen to help their fellows turn to accidents and illnesses as an obvious opportunity to serve Policemen, firemen, railwaymen, and pitmen, engaged in hazardous work, voluntary institutions whose members attend public meetings, young men and women who climb mountains or fly, and indeed anyone who takes his car out of the garage, may be the first to see someone suffer injury, or may suffer one himself The doctor who tries to repair the damage often appears late in the succession of those who have contributed in some way to its treatment

It is part of the system of training first-aiders that advice shall be simple, clear, and dogmatic Hesitancies must be suppressed, and every dilemma must be resolved before instructions on first-aid are laid down This book will be the ultimate authority for many people for many years to come

The first and perhaps the greatest dilemma facing the authors of such a book is between simplicity and comprehensiveness A simple manual reaches a wider public, and, because first-aid is needed widely, some would say the barest minimum of information will do the greatest good This argument influenced the Priory of Canada when they published *Fundamentals of First Aid* [2] three years ago In this book Dr Robert A Mustard discarded all discussion of shock, and all description of pressure-points He condemned the tourniquet outright as a first-aid instrument, discouraged the use of bandages to stabilise fractures of collar-bone, jaw, ribs, pelvis, and some others, and in many other ways shortened the course and limited the exercises which have been practised throughout this country for generations Our own book, on the contrary, contains more material than it did thirty years ago, although its size, because of streamlining and simplification, is not much increased It prefers comprehensiveness, encourages the maintenance of a corps d'élite, aims particularly at the team which trains diligently, and fosters the cult of first-aid training by devoting, for instance, eighteen pages to stretcher exercises

Yet in many ways this new book brings the practice much closer to modern conditions Although sections on civil defence and labelling of casualties in war might indicate that it is becoming more complicated, the improvement in communications, hospital services, and medical care make the first-aider's task easier under our present organisation Elaborate splinting of fractures may not be necessary if a hospital is near, and we are warned not to delay disposal of a casualty by work which is to be undone a few minutes later Experts in first-aid will still argue over occasional details Holger-Neilsen takes definite priority over Schafer in artificial respiration, though both methods are well described We are still to transport the patient with a fractured spine on his back, though an appendix instructs on the prone position "if it is unavoidable" Every casualty officer will have sympathy with the first-aider who is being coached in differentiation between twelve or more listed causes of unconsciousness

Dr L S Potter's editing has had much excellent writing to draw on from previous editions, but we detect a new and vivid pen in places "the whole spine is *strapped together* [our italics] by bands of strong fibrous tissue" Every medical student might well prepare himself for more detailed studies by reading the simple survey of human anatomy and physiology at the beginning This work is, of course, not intended primarily for doctors, though no doctor would lose by studying it *Many* thousands serve the ends to which doctors are dedicated, and it is here to serve them The ancient Hospitallers of St John and their kindred brotherhood the Templars (whose seal showed two knights upon one horse) would have approved this combination of forces in a single vehicle, in pursuit of a single aim

THE COMMON COLD

IN this coming season of mists and mellow fruitfulness our thoughts turn once more to influenza and the common cold After last year's bumper harvest the influenza virus may decide that the soil is too heavily immunised But that hardy old perennial, the common cold, is unlikely to give us any peace, and as the schools open, we can expect it back again

Dingle[1] gives us a timely reminder of our ignorance of the subject in his presidential address to the American Association of Immunologists In a group studied by Hope-Simpson,[2] each person has on average 7 colds a year, and therefore spends practically one day out of every five coughing and sneezing Many of us will react to this by protesting that we hardly ever catch cold, and we will support this by describing our favourite prophylactic or remedy If so, we shall be doing just what Dingle says we shall do, because ignorance of the cause, predisposing factors, and treatment of the common cold is so great that the field is wide open for theories and unproven assertions One of the commonest—that colds are caused by chilling—is beginning to weaken under constant experimental attack, and it now seems clear that a feeling of chilliness is often an early symptom of infection rather than a causal or predisposing factor But it may take some decades before the public are persuaded of this Dingle also emphasises our ignorance of the methods of natural transmission of colds and of factors of resistance and susceptibility Psychological factors in resistance to colds are now being invoked, and, if this seems an unlikely association to some, it is worth reflecting that Dingle was himself responsible for a most careful trial from which it emerged that, three weeks after having been infected with a common-cold filtrate, volunteers showed no specific immunity to the same virus Attack-rates are higher in children and tend to decrease with age, but it is not yet established whether this reflects increasing immunity or diminishing exposure to virus

If the disease is full of puzzles, the virology, according to Andrewes in a De Lemar lecture,[3] is not without its problems New techniques of virus isolation and study continue to reveal more and more viruses, and often the biological characters of the virus are known in some detail before its epidemiological significance is understood Besides the influenza viruses and adenoviruses, new viruses are being recovered every few months from people with upper-respiratory disease of one kind or another The question arises whether new pathogens are being discovered, or whether we are just beginning to amass a collection of relatively harmless virus commensals which correspond to the bacterial commensals isolated in the first flush of enthusiasm for detailed bacteriological investigations So far none of the viruses isolated has shown a clear association with common colds, but Andrewes nevertheless raises the question whether the common cold will be found to be a fairly common response to infection with a large number of different viruses, or alternatively where there is a single common-cold virus Until now, attempts at continuous cultivation of it (or them) in the laboratory have not proved successful In this phase of rapid advances it will be surprising if the common-cold virus resists cultivation for very much longer—although, even if the virus gives in quite soon, we may still spend many years wearing our flannel underwear to keep off chills Meanwhile it is noteworthy that Dr J Morrison Ritchie, whose latest report appears on p 699 of this issue, has confirmed his earlier observation that full development of a cold can often be prevented by administration of an antibiotic at the onset

POSTNECROTIC CIRRHOSIS

EVER since 1895, when Marchand[1] first described the development of nodular hyperplasia of the liver after an attack of acute yellow atrophy, the relation of this nodular lesion to other forms of cirrhosis has been disputed Lichtman[2] has been outstanding among those who refuse to regard it as an example of true hepatic cirrhosis, on the grounds that progressive replacement of parenchymal cells by scar tissue is the essence of true cirrhosis and the nodular hyperplasia that follows massive hepatic necrosis seems to represent the static end-result of a single acute episode On the other hand, Mallory,[3] Karsner,[4] and many others have long regarded nodular hyperplasia as a true cirrhosis, to which the term postnecrotic cirrhosis is usually applied Delay in resolving this difference of opinion has been due to many factors, but principally to the relative rarity of the condition and to our ignorance of the ætiology of almost all forms of hepatic cirrhosis Now a study by MacDonald and Mallory[5] of the 221 cases of postnecrotic cirrhosis that came to necropsy at the Boston City Hospital between 1917 and 1956 has provided convincing evidence that the disease is progressive

Unfortunately, this study throws little fresh light on ætiology Exposure to known liver poisons was negligible Malnutrition apparently played only a minor role, since nutrition could be regarded as adequate in over half the patients, but in 41% chronic alcoholism was a feature The outstanding result of the analysis of the case-records was the possible association with virus hepatitis No less than 24% gave a history of a previous attack of hepatitis or jaundice, and a further 44% had received multiple parenteral injections for one reason or another, thus exposing themselves to the risk of homologous-serum hepatitis But even in the former group, in only a third of the patients was the relation of the cirrhosis to the clinical attack of hepatitis reasonably direct In the other two-thirds there was an average interval of over fifteen years between the earlier attacks of jaundice and the appearance of symptoms unequivocally associated with cirrhosis The only justifiable conclusion from these data is that viral hepatitis is the most likely agent responsible for the majority of cases of postnecrotic cirrhosis, and the undoubted increase in incidence of this type of cirrhosis in recent years harmonises with this conclusion Yet it is not easy to understand why clinical manifestations of cirrhosis appear so long after the hepatitis Possibly the virus persists through the intervening years, causing slowly progressive damage that eventually emerges above the clinical threshold with hæmatemesis or ascites, or

else the virus persists for months or years without producing any damage until, owing to some change in host-virus relationship, progressive necrosis of the infected liver cells occurs and leads to progressive cirrhosis A third possibility has been suggested if the initial damage produced were severe enough the resultant scarring might lead to vascular disturbances within the liver and thus to further necrosis and scarring Glynn[6] suggested a similar sequence to explain the irreversible stage of cirrhosis in rats that have received twice-weekly injections of carbon tetrachloride[7]

The ætiology and pathogenesis of postnecrotic cirrhosis are still far from clear As MacDonald and Mallory point out, the main impediment is the failure at present to reproduce virus hepatitis in an animal other than man Success here could lead to rapid progress in our understanding of postnecrotic cirrhosis

CHORIONCARCINOMA AN IMMUNOLOGICAL APPROACH

Because the immune processes in the causation of hæmolytic disease of the newborn have been determined, it is now possible to await its occurrence with some confidence and to set in motion the necessary treatment at the moment of choice Just under two years ago it was shown that Hashimoto's disease of the thyroid gland was caused by a cellular antibody reaction to leakage of thyroglobulin out of the thyroid acini[8]

This year a first attempt has been made[9] to apply the knowledge gained by P B Medawar and his associates in relation to tissue immunisation to the treatment of chorioncarcinoma Even though the degree of success in this particular patient is hardly capable of scientific interpretation, because many additional treatments were employed, the ideas which underlay the attempt can be applied to other patients and could lead to a revolution in approach to this dramatic and distressing tumour

The tissues of a mother and a child are not compatible, a skin graft from child to mother behaves as a homograft, not an autograft, because of the presence of paternal antigens in the cells of the graft Since chorioncarcinoma originates from fœtal tissue, half the genes in its cells are derived from the father Doniach et al considered, therefore, that deliberate immunisation of a patient suffering from chorioncarcinoma by her husband's cells might induce or enhance her tissue incompatibility (homograft immunity) towards cells containing the husband's genes and might thereby check or even destroy the tumour Immunisation was induced by intradermal or subcutaneous injection of white blood-cells from the husband on eleven occasions The earliest injections produced an immediate local reaction which subsided within a week The patient was tested by two means in an attempt to demonstrate tissue immunity to the husband's white blood-cells Firstly, skin grafts were made from the patient, her husband, and another donor The autograft survived but the two homografts disintegrated —the husband's more rapidly than the donor's Secondly, leucoagglutinins were demonstrated to a titre of 1 in 64 against the husband's white blood-cells These facts were regarded as evidence that immunity had developed in the patient against her husband's cells

During and after the period of immunisation and testing, the patient, who had had hysterectomy for proved chorioncarcinoma, developed vaginal recurrence and lung metastases, both of which were treated by deep X-ray therapy, with temporary improvement When extension of the pulmonary metastases was observed, four courses of treatment with an anti-folic-acid preparation were instituted, subsequently the lung shadows disappeared, and the symptoms were dispelled This was two years after the start of symptoms Doniach et al consider that immunity may have helped the action of the anti-folic-acid drug

Theoretically, it is to be expected that the very presence in the mother's uterus of chorionic cells, half of whose genes are derived from the father, will normally evoke a maternal tissue immune reaction which might check or modify their growth Possibly, when chorioncarcinoma develops and spreads, this mechanism is lacking or in some way modified Where the tumour spreads and spontaneously regresses, as it does in some cases, immunity may develop late or some kind of blocking mechanism may operate temporarily There are "infinite gradations of antigenic relations between the components of different tissues and different species"[10] There is clearly scope for further experimental study of these relations in chorioncarcinoma

DEFINING OVULATION-TIME

From America comes the suggestion that the time of ovulation can be simply and accurately pinpointed by the use of strips of tape or paper impregnated with the enzyme glucose oxidase, which, when placed against the cervix, will demonstrate by change of colour from yellow to green the increase in glucose content of cervical mucus known to occur at the time of ovulation Some physicians require the patient to visit the office daily for several days about the time when ovulation is expected[10] 'Tes Tape' is applied to the mucus cascade and the colour change in the tape is noted What happens, or should happen, when ovulation is imminent or has just occurred, is a change of colour to brilliant green and later to a darker green, indicating that coitus in the next 12 hours is likely to prove fruitful Doyle[11] of Boston, thinks that the tes tape can equally well be applied by the patient herself, using a cylindrical cardboard tampon The woman inserts one of these for a few minutes daily from the 8th to the 16th day of the cycle, and, unless she is colour-blind, can see when the colour changes to green She and her husband can then take appropriate action according to whether they want conception to occur or not Correlation of these colour changes with other ovulation indicators (shift in basal temperature, *Spinnbarkeit*, positive palm-leaf reaction, secretory change in endometrium) has been established Doyle has gone further and has demonstrated by colpotomy and at laparotomy the presence of a recently ruptured follicle and the production of a similar green colouration of tes tape dipped in spilled follicular fluid recovered from the pelvic peritoneum[12]

The efficacy of this new method of dating ovulation can be confirmed only by trials on many volunteers *If further experience* shows it to be accurate it should prove of value not only in the treatment of infertility, but also to those who practise the *rhythm* method of birth control

We report some preliminary details of a case of craniopagus twins Two features believed to be unique are that the mother gave birth to one single normal healthy baby at the same time as the conjoined twins and that one of the conjoined twins has had congenital hypertrophic pyloric stenosis The last case known to have been born in England was described in *The Lancet* exactly thirty years ago by Cameron (1928)

Craniopagus twins are the rarest of all conjoined twins, estimated at 1 in every 2 to 4 million births by Robertson (1953), who analysed Tartuffi's figures Of 117 conjoined twins 86 were joined anteriorly by the thorax (thoracopagus), 22 posteriorly in the sacral area (pygopagus), 7 caudally by the lower abomen (ischiopagus), and only 2 by the skull (craniopagus) The present case is the 42nd to be recorded in the available literature, but the 6th since 1949, which may reflect no more than the present age's greater ability to read and write

The usual fate of these babies has been death, sometimes in the first week, nearly always by the end of the first year One set, the first on record, 2 girls joined by the forehead born in Bierstadt in 1495 (Münster 1559), lived until the age of ten years, when one died The dead partner was cut away and the second died shortly after

In Cameron's case an emergency separation was attempted by Mr L Bromley on the twelfth day because one was obviously deteriorating, but both died during the operation Cameron commented that if the intradural spaces communicate, attempts at separation are useless Technical progress in neurosurgery, plastic surgery, and anaesthetics has altered the prognosis to some extent

The first success was reported by Sugar and Grossman in 1953 One baby died one hour after separation, but the other survived and was developing well at eighteen months Voris et al (1957) reported successful separation with satisfactory condition of both twins at two years and four months These three sets resemble in the photographs the set reported here, the main junction being between the parietal bones (c parietalis) The most recent paper, by Baldwin and Dekaban (1958), concerns craniopagus twins joined mainly at the forehead (c frontalis), a rarer type in which the actual area of the junction is smaller The twins were successfully separated in 1956 and both were within the normal range on their first birthday

Separation with survival of both of the twins can be successful only if sufficient tissue is present for two separate individuals The smaller the area of fusion the better the outlook. The tissues involved are the brain which has been adequate and virtually separate in hitherto reported cases The covering membranes, especially the dura mater, are usually deficient over some part of the fused area The arteries are expected to be independent, but the exact state of affairs must be established by angiography The most probable stumbling-block is large venous communication. Skin to cover the vertex can be prepared without great difficulty The problem of the replacement of skull bones has not yet been solved In only two cases so far reported have both of craniopagus twins survived (Voris et al 1957, Baldwin and Dekaban 1958), in Sugar's case (Grossman et al 1953), where there was a closer fusion, a common sagittal sinus made survival of both impossible, and from the description this case resembles the present one most closely.

Case-record

Obstetric History

The mother attended hospital for her fourth pregnancy after ten weeks' amenorrhœa. She was a healthy woman with a childhood history of scarlet fever, measles, and mumps, both she and her husband are of European descent Her first pregnancy had resulted in an abortion Two years later she was delivered by forceps at the forty-third week of pregnancy of a stillborn female infant weighing 3670 g (8 lb 1$^1/_2$ oz), postmortem examination showed that the baby was normally formed but had died of a massive aspiration of meconium

After a further two years she was admitted at term for a surgical induction of labour under general anæsthesia As she was not in labour in forty-eight hours after rupture of the membranes, a lower-segment cæsarean section was performed by J S T, delivering a boy weighing 9 lb 1$^1/_2$ oz (4125 g) in good condition

When first seen in her fourth pregnancy she was a fit woman, aged 36 years, height 5 ft. 5 in She had slight varicose veins of the right leg and a recent rash on her fingers which she attributed to a wasp sting At every antenatal attendance the height of the uterine fundus was noted to be greater than the duration of the pregnancy warranted. When Mr J D S Flew examined her at eighteen to twenty weeks the uterus was the size of a thirty-week gestation Radiographic studies revealed triplets (fig 1) and are reported in detail below At the thirty-first week the abdominal girth was 46 in, and at the thirty-third 48 in Symptoms of pre-eclamptic toxæmia were present for the first time at thirty-five weeks the blood-pressure was 145/90 mm. Hg and there was a trace of albumin in the urine and slight peripheral œdema, so that the patient was kept on strict bed rest. The next day these abnormal signs had disappeared

During the morning of delivery there was a small but definite show of blood per vaginam The membranes were intact. The patient was well, three fœtal hearts were heard, and there were no uterine contractions It was decided to deliver by cæsarean section that day because of the previous history and the known presence of fœtal abnormality in a multiple pregnancy Under general anæsthesia (thiopentone, suxamethonium, gallamine, and cyclopropane) a classical section was performed. The first baby was delivered by the breech at 6 45 P M, he cried at once and was in excellent condition The second amniotic sac was opened and twin boys joined at the cranial vault were delivered simultaneously at

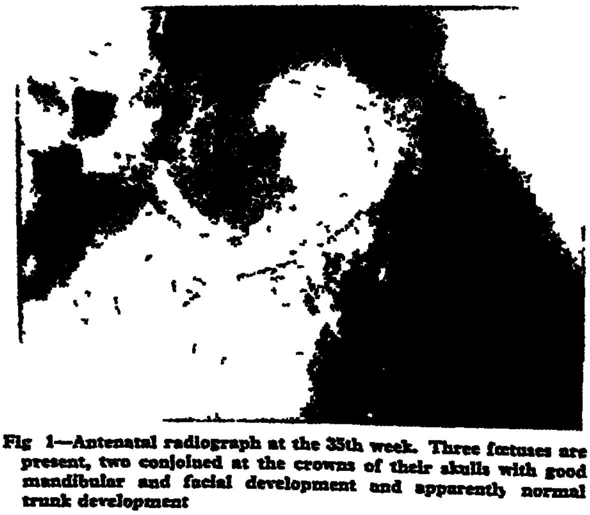

Fig 1—Antenatal radiograph at the 35th week. Three fœtuses are present, two conjoined at the crowns of their skulls with good mandibular and facial development and apparently normal trunk development

6 48 P M Both cried at once None of the babies presented any resuscitation problem, but in all mucus was cleared from the air passages Ergometrine 0 5 mg was injected intravenously into the mother and the same dose directly into the uterine muscle after the delivery of the babies The previous lower segment operation scar was palpated and estimated to be 3 mm thick The uterine cervix was dilated to the diameter of two fingers' breadth Postoperative progress was uneventful except for pyrexia of 100°F on the first and third days

The placenta (fig 2) was an intimately fused organ with two amniotic sacs which did not communicate

Antenatal Radiographic Studies

The first abdominal radiographic studies at the nineteenth week showed three fœtal spines, indicating the probability of triplets That only two skulls were seen, indicated some fœtal anomaly, possibly anencephalus At the 28th week the radiographs were interpreted as showing one normal fœtus and a twin with two separate trunks and a gross cranial fusion At the 35th week immediately before delivery by cæsarean section craniopagus twins were clearly seen with two normal trunks and good mandibular and facial development The third fœtus showed no abnormality (fig 1)

The Triplets

The first baby (a male weighing 5 lb $9^{3}/_{4}$ oz , 20 in long, skull circumference $13^{1}/_{2}$ in) has appeared completely normal throughout He was successfully breastfed and at twelve weeks weighed 13 lb 12 oz

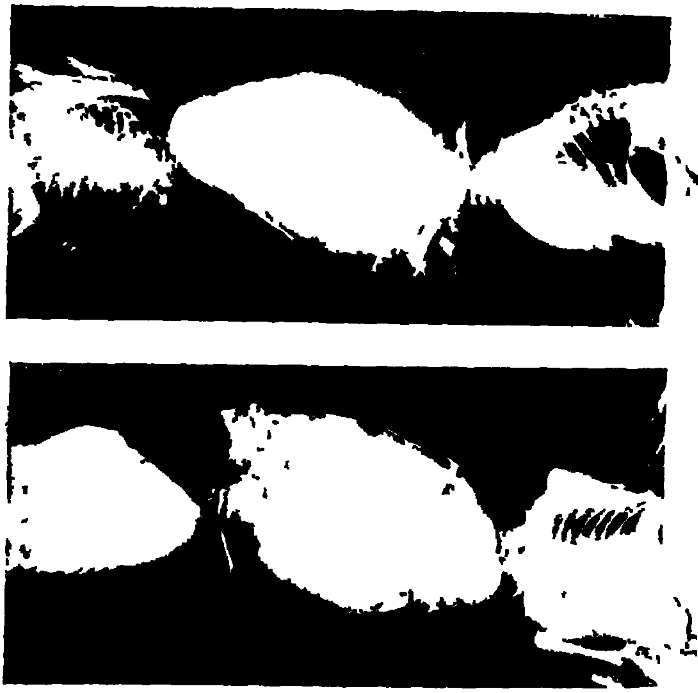
The craniopagus twins, also males, together weighed 9 lb 12 oz The vertices have virtually coalesced so that one skull cannot be moved on the other They lie in a straight line, their long axes twisted through somewhat more than a right angle This allows both to lie on the right or on the back while the face is turned half right When on the left side the neck is strained and they are not comfortable

General examination reveals no other abnormality Rectal temperature readings differ and so do pulse and respiration rates, which do not synchronise Simultaneous blood-pressure readings show 60 mm Hg systolic in one and 50 mm in the other Both are blood-group O, rhesus positive figures for Hb, white-cell count, and differential leucocyte count are not identical Electrocardiograms differ in rate and pattern, both having a physiological degree of right preponderance Electroencephalograms soon after birth, kindly carried out by Dr G Pampiglione, showed the brains to be separate

Fig 2—The placenta

The twins are two distinct individuals with independent behaviour and personality One may cry or feed while the other sleeps One is bigger and stronger, but both are full of charm and mentally alert, and they do not appear to upset each other

Clinical progress of the smaller twin has been interrupted by severe vomiting from eight to twelve weeks Projectile vomit of curds with visible gastric peristalsis, and a palpable pyloric tumour, supported the diagnosis of congenital hypertrophic pyloric stenosis Symptoms were relieved by a course of atropine methonitrate ('Pylostropin')



Figs 3 and 4—Radiographs shortly after delivery, taken in two planes at right-angles There is craniopagus with parietal fusion over a wide area The long cranial axes of the two heads are approximately at right angles to one another Facial bone formation of both appears perfect

In radiographs of the conjoined skulls (figs 3 and 4) no bony shelf can be seen between the vertices Parietal fusion exists over a wide area The long cranial axes of the two heads are approximately at right angles to each other Facial bone formation of both appears perfect

Discussion

Questions of ætiology are well discussed in some of the papers we have quoted, especially by Robertson (1953) We can only add that the presence of pyloric stenosis in one of the twins exemplifies the principle pointed out by Aird (1954) that conjoined twins " are seldom so precisely identical as separate monovular twins are " The future action in this case could not be better planned than in accordance with Aird's further statement that " however great the risk of the death of one or both children, it would seem that operation should nearly always be undertaken if the children are known each to have a full complement of the organs and tissues necessary for separate life "

In Cameron's case emergency operation failed, in Barbosa's (1949) both died three hours after operation, in Robertson's (1953) operation had to be abandoned The three latest reports of partial or complete surgical success are quoted above In this case great difficulty is likely to be encountered and the final separation will not be attempted before the first birthday To achieve separation with the survival of both twins will require not only great prowess on the part of the surgeons but also sufficient tissues for two independent beings To achieve one survivor will amply repay the great demands on the skill, the patience, and the emotions of all concerned Fortunately it was possible to avoid publicity in this case for more than three months, giving the parents some time to recover from the immediate emotional shock

Attempts to satisfy public curiosity about previous conjoined twins put a strain on parents, doctors, and nurses. It is hoped that in this case newspapers and their representatives will exercise restraint and allow all those involved to conduct a hazardous undertaking in calm and peace. The authors (and the parents, with whom it has been discussed) feel that no photograph of the conjoined twins should under any circumstances be published during the lifetime of either twin.

POST-HOSPITAL ADJUSTMENT OF CHRONIC MENTAL PATIENTS

G. W. BROWN
B.A. Lond

G. M. CARSTAIRS
M.B. Edin., M.R.C.P.E., D.P.M.

GILLIAN TOPPING
M.A. Lond

From the Medical Research Council Social Psychiatry Research Unit, Institute of Psychiatry, Maudsley Hospital, London, S.E.5

UNTIL recently, once a patient had stayed for two years continuously in a mental hospital, his chances of discharge were low (Kramer et al. 1955, Carstairs et al. 1955) and would become progressively lower until, by the eleventh year of stay, they would be about 1 in 100 (Registrar General 1955). This situation may now be changing.

The Royal Commission on the Law Relating to Mental Illness (1957) stated a new viewpoint:

> "There is increasing medical emphasis on forms of treatment which can be given without bringing patients into hospital as in-patients or which make it possible to discharge them from hospital sooner than was usual in the past. It is not now generally considered in the best interests of patients who are fit to live in the general community that they should be in large or remote institutions such as the present mental or mental deficiency hospitals . . . No patient should be retained as a hospital in-patient when he has reached the stage at which he could return home if he had a reasonably good home to go to."

Brill and Patton (1957) and Kramer and Pollack (1958) show that in the United States in 1955–56, the year in which the use of tranquillising drugs became widespread in that country, the number of patients resident in State Mental hospitals declined, in reversal of a long-established trend. Brill and Patton showed that in New York State this could largely be ascribed to an increase in the number of discharges, especially affecting patients who had been more than two years in hospital. Neither Brill and Patton nor Kramer and Pollack (1958) indicated the level at which patients were functioning after their discharge from hospital.

Usually a psychotic patient discharged after a prolonged stay in hospital is not completely recovered but carries at least some residual disability. His remaining in the community will depend partly on the nature and degree of this psychiatric handicap and partly on the social environment to which he returns.

There have been many follow-up studies of former mental patients in general, and of patients with particular diagnoses or who have been exposed to particular forms of treatment (in most of which a stay in hospital of more than two years is claimed to carry a relatively unfavourable prognosis), but we have been able to trace only two studies which dealt specifically with the fate of long-stay patients after discharge from hospital.

Smith (1946) reports the outcome of 56 females who had been in hospital at least four years before discharge from St. Hans Hospital, Denmark. 54 of these still had symptoms, most required considerable help from social agencies. During the follow-up period (ranging from nine months to three years) 6 of these patients were readmitted and 1 committed suicide. Of the 49 who remained in the community only 6 were self-supporting.

Stringham (1952) reported the outcome of 33 patients discharged after an average stay in hospital of twelve years. 15 returned to hospital, but 6 of these were subsequently discharged again. Of the 24 still in the community about two years later only half were self-supporting. Stringham suggested that opposition on the part of the patient's family was the principal obstacle to their remaining in the community, and their ability to obtain gainful employment was the strongest positive factor in those who succeeded.

The present study was designed to ascertain the outcome of long-stay patients discharged from mental hospital and to look for factors in their history and in their subsequent social experiences which were associated with their level of adjustment in the community.

Method of Investigation

Selection of Cases

The population consisted of all those male patients who were discharged by any means from seven mental hospitals in or near London between July, 1949, and June, 1956, and who fulfilled the following criteria:

(1) Subjects of the United Kingdom by birth.
(2) Aged 20–65 on discharge.
(3) Had been in hospital two years or more before discharge.
(4) Not known to have gone to an address outside the Greater London Area.

Patients who died in the first year of discharge were excluded from the sample. There were 3 such deaths during the period, all of them natural. Patients who were out on trial for more than three months consecutively were included as from the end of the three-month period.

Selection of Informants

Whenever possible the primary informant was the housekeeper of the domestic group to which the patient went on leaving hospital—typically his mother, wife, or sibling, but in some cases his landlady. Any patient living alone was himself interviewed.

Follow-up Interview

An interview schedule was prepared covering 160 items, selected on the assumption that they might have a bearing on the patient's outcome. The schedule was usually completed for each patient after a study of the hospital case-notes and an interview with the primary informant lasting an hour to an hour and a half. Sometimes more than one person was interviewed.

The conduct of the interview was not formalised, but interviewers used a check-list to ensure that all the items had been covered. Each of us took part in interviewing, with weekly meetings for discussion of possible ambiguities in the recording of particular items, in this way it was hoped to ensure uniformity in the recording of data from the interview.

Measures of Outcome

For the purpose of analysis each patient's outcome was assessed in terms of the following criteria

(1) *Duration of discharge period* —" Success " (s) was defined arbitrarily as staying out of hospital for at least a year, readmission for more than a month in the year following discharge was counted as " failure " (F) This criterion of success proved to be relevant, especially for schizophrenia Since information was obtained at intervals of one to six years after discharge, it was possible to calculate that, of the patients who relapsed during the six years, 74% of the schizophrenics and 58% of the non-schizophrenics did so within the first year

(2) *Level of social adjustment* —All patients counted as successes were rated by a scale of social adjustment, in which 1 point was given for each of the following three items (*a*) being gainfully employed for five of the last six months in the first year of discharge, (*b*) being able to look after himself as regards appearance, dress, and use of money, and (*c*) showing adequate interpersonal relationships—i e, without gross disturbances such as violence, paranoid ideas, or extreme withdrawal

A score of 3 points rated " full adjustment ", 2 points " partial adjustment ", and 1 or 0 points " poor adjustment "

Some Characteristics of Population Studied

From the records of the seven hospitals 240 men were identified who fulfilled the necessary criteria, and schedules were completed for 229 (95%) Follow-up information could not be obtained for 11 of the original population, of whom 9 were diagnosed as schizophrenic, 1 as depressive, and 1 as psychopathic A search of the records of the Board of Control did not reveal evidence that any of these 11 patients had been readmitted to mental hospitals since discharge, all have been omitted from our analysis

Diagnoses

The diagnoses of the population studied were as follows

	No of cases
Schizophrenia	156
Depression	26
Epilepsy	18
Organic psychoses	10
Psychoneuroses	9
Mania	5
Other	5
Total	229

If the population is then divided into two main categories " schizophrenia " and " other " it can be further described in terms of the following factors

Age —The mean age of schizophrenics was 39 4 and of those with other diagnoses 45 0, in both the age range was 20–65

Length of stay —The two main categories of diagnosis had comparable lengths of stay for the admission to hospital which preceded this discharge, with a mean of 6 5 years (range 2–30 years)

First admissions —31 4% of schizophrenics and 43 8% of those with other diagnoses were first admissions

Marital status on admission —77 6% of the schizophrenics and 42 5% of the others were single on admission

Patients' Condition on Discharge

Before assessing the patients' outcome one would like to know as accurately as possible their mental state at the time of discharge, but in this retrospective study precise information on this point was unavailable Some measure of the patients' mental state was, however, provided by the following observations

(1) *Whether discharged on or against medical advice* —31% of schizophrenics and 15% of the others were discharged against advice

(2) *Whether recorded as recovered, relieved, or not improved on discharge* —Of the schizophrenics 14% were discharged as recovered, 65% as relieved, and 21% as not improved, for the other patients the proportions were 13% recovered, 7 relieved, and 10% not improved

(3) *A rating of the patients' level of disturbance of behaviour* while living in the community a year after discharge or just before readmission in the case of failures —This was estimated on the basis of questions about ten specific features of the patient's behaviour and was rated in three categories Patients who showed only minor peculiarities, or none, were rated " nearly normal " Patients with evident peculiarities which did not, however, preclude their moving about in society were rated " moderately disturbed " (e g, a patient with hallucinations and paranoid ideas who found a succession of jobs to quit them abruptly in response to his delusions) Pati showing more severe disturbances of behaviour, such as to be cited in recommending certification and interfered seriously with his social life, were rated " severely disturbed " It w be appreciated that this rating made at a later date can only giv a somewhat conjectural (but still useful) indication of patient's condition on discharge

Of the schizophrenic patients 39% were rated near normal, 35% moderately disturbed, and 26% severe disturbed, of the remainder 45% were rated nea normal, 36% moderately disturbed, and 19% severe disturbed

Findings

Measures of Outcome

32% of the total population were failures and 68 successes, percentages were comparable for schizophre and other diagnoses

Table I shows that other diagnoses have a sligh superior but non-significant (p>0 1) distribution social-adjustment scores 26% of the total populatior showed a very satisfactory or full social adjustmen (93% of these were rated nearly normal in behaviour), whereas 22 8% made a definitely poor adjustment, 18 9% were intermediate between these two social adjustment categories

TABLE I—SUCCESSES AND FAILURES

Diagnosis	No of cases	Successes (%) by level of social adjustment			Failures (relapse in 1st year) (%)
		Full (3 points)	Partial (2 points)	Poor (1 and 0 points)	
Schizophrenia	156	25 2	17 4	25 8	31 6
Other	73	28 8	21 9	16 4	32 9
Total	229	26 3	18 9	22 8	32 0

Table II shows the distribution of the three-fo behavioural ratings by schizophrenia and other diagnose and by success or failure 40 8% of the total populatio were rated nearly normal, 35 2% moderately disturbe and 24 2% severely disturbed The ratings are related success or failure

Relation of Outcome to Clinical State on Discharge

The two indicators obtained from patients' ca notes (" discharged against advice ", and " recovered " relieved ", or " not improved " on discharge) were br related to our criteria of outcome (With the crite of success or failure both showed a coefficient of co

TABLE II—BEHAVIOUR

		Success	Failure	Success	Failure	Success	Failure
Schizophrenia	156	37 8	1 3	23 1	11 5	7 7	18 6
Other	73	38 9	5 6	20 8	15 3	6 9	12 5
Total	229	38 2	2 6	22 4	12 8	7 5	16 7

gency* of 0 24, p<0 001, with the three-fold social-ustment rating the coefficients were 0 32 and 0 26 pectively, p<0 01)

The rating of patients' level of behaviour was also related with outcome, both in terms of success or lure, where C was 0 50 for the schizophrenics and 0 38 the others (p<0 001), and of social adjustment, which s rated in part on observations of patients' behaviour It is therefore clear that, in assessing subsequent ationships between clinical and social factors and the tients' outcome, a first precaution must be to ensure at the relationship is not a reflection of the patients' fering levels of clinical state at discharge In many of e following instances the above indices of clinical state discharge have been used to counteract crude clinical bias

e-discharge Items

Number of previous admissions—The relationship of is item to outcome differs for the two diagnostic cate-ries, schizophrenia and other diagnoses 31% of the hizophrenics were first admissions, and only a few 7%) had been in hospital three or more times before his small category contained relatively more failures 2 successes and 15 failures, p<0 01) but showed no lationship with social-adjustment scores In contrast, her diagnoses had a greater number of first admissions 4%), of whom only 3 of 32 failed In this diagnostic oup the number of failures increased significantly in the roup of patients who had been in hospital before, compared with the first admissions (21 of 41 failed, p<0 001) gain no relationship was found with social-adjustment cores

Length of key admission—For neither schizophrenia or other diagnoses did the length of key admission bear ny direct relationship to success or failure, nor for other diagnoses did it relate to social-adjustment scores However, for schizophrenia those with poor adjustment were mainly concentrated in those with less than ten s' stay (p<0 05), although trends are not striking, chizophrenics with longer stay in hospital had a slightly superior outcome

Age at discharge—Only 2 of the 17 schizophrenics aged more than 55 failed Otherwise age bore no relationship to success or failure either for schizophrenia or for other diagnoses As regards social adjustment, however, the younger schizophrenics, aged 20–34, were significantly more often poorly adjusted (p<0 01), whereas other diagnoses showed no such relationship

Pre-admission levels of social achievement—Various measures of pre-admission achievement were obtained in e areas of employment and economic responsibility uperior achievement was usually significantly related to ost-hospital success and to higher social-adjustment cores The relationships still remained when clinical tate at discharge was taken into account

Post-discharge Experiences and Outcome

The two most important factors in the social experience a discharged patient were whether the patient worked not and with whom he lived

Employment—Table III shows an important relationship between employment and success or failure 41% of the population worked for six months or more, and of these 97% succeeded, whereas of the 43% who were never employed only 46% succeeded Of the 89 successful patients who worked for most of the year a third were rated as either moderately or severely disturbed, and many of the others had residual symptoms, indicating that the presence of psychotic symptoms was not necessarily a serious obstacle to their employment

TABLE III—EMPLOYMENT

Employment	Successes	Failures	Total
6–12 months	89	3	92
1–6 months	19	18	37
Unemployed (includes those working less than a month)	44	52	96
Information inadequate for rating	4		4
Total	156	73	229

Type of living group—The results so far presented take on new significance when tabulated by type of living group to which the patient returned The significance of the social setting on discharge has been more fully analysed by one of us (G W Brown, unpublished), only the chief points are noted here

Table IV shows that schizophrenics who returned either to parents, wives, or hostels relapsed in the first year significantly more often than did those returning to other kin (mainly siblings) and lodgings Those who did succeed while living with their parents had significantly lower social-adjustment scores than patients living with other kin or in lodgings Fewer living with parents were employed compared with the successful patients living with their wives, with other kin, or in lodgings

Relatively more patients rated not improved on discharge went to stay with their parents or in hostels, but these differential failure rates and social-adjustment scores still persisted at a significant level when this bias was controlled This indicates that the type of living group to which a patient goes after leaving hospital may have an important bearing on his subsequent career, whatever his residual disabilities are

Psychiatrists are familiar with the mother who tolerates, and perhaps even encourages, an attitude of child-like dependence in her schizophrenic son This kind of relationship was especially common in the 53% of unemployed schizophrenics living with their parents and was very rarely found in other types of living group Perhaps it is not always beneficial for a schizophrenic to return to the close emotional ties of a parental or marital household

There was some evidence that behaviour deteriorated more in schizophrenic patients who went to parental and marital groups For example, the relative incidence of violent outbursts and displays of temper was significantly greater in these groups, whereas other psychotic manifestations (e g, delusions) were more often reported for patients living with other kin and in lodgings

Where a schizophrenic lived with his parents and was unemployed, with the result that he was brought into close contact with his mother all day, he was likely to fail, but if he or his mother were away at work for part of each day, he was more likely to succeed

TABLE IV—WHERE LIVING

Where living	Schizophrenia			Other diagnoses		
	Successes	Failures	Total	Successes	Failures	Total
Hostel	6	7	13	4	7	11
Hostel (supportive)	1		1	4	3	7
Parental	55	31	86	8	8	16
Marital	7	7	14	16	1	17
Other kin (mainly siblings)	20	4	24	9	3	12
Lodgings	18		18	8	2	10
Total	107	49	156	49	24	73

---

* Uncorrected coefficients of contingency derived from χ^2 results are used. The maximum for a 2 × 2 relationship is 0 707 and 3 × 3 is 0 816

TABLE V—MARITAL STATE

Marital state	Schizophrenia		Other diagnoses	
	Successes	Failures	Successes	Failures
Married	7	7	16	1
Widowed, separated, or divorced	16	2	11	14
Total	23	9	27	15

The relationship of outcome and post-hospital living group was less clearcut in the patients with other diagnoses, but there was some evidence that they, unlike the schizophrenics, tended to do better in situations involving close personal relationships. For example, table V shows completely contrary results for patients of the two diagnostic groups in respect of their marital state at discharge.

Of the 16 patients with other diagnoses who succeeded in a marital setting 7 were unemployed. In contrast, of the 7 schizophrenics who succeeded in a similar environment 6 were employed. These figures suggest that wives found it easier to tolerate a state of dependence in patients of the former group. A factor which *may* have contributed to this greater tolerance was the presence of a physical ætiology or physical handicap in 6 out of the 7 unemployed men in this group. These patients were easier to live with and responded more positively to the support offered to them than did the schizophrenic husbands, whose behaviour in several instances was much disturbed.

Aftercare

Only 37 of the 229 patients (16.2%) were reported to have attended an outpatient clinic for follow-up treatment. One or more visits were paid by a psychiatric social worker to 39 patients (17.0%). In neither of these small groups did the outcome differ significantly from that of the remainder.

Social Liabilities Incurred

To reach a just estimate of the outcome of these patients it was necessary to take into account not only their success in avoiding relapse and in attaining a fair level of social adjustment but also the consequences to other persons of the patients' return to living in the community. In some instances the patient's success was bought at the price of occasioning severe distress to others in his household.

A three-fold rating was therefore made of the amount of hardship which the patient's presence imposed on other members of his living group. The rating "severe liability" was reserved for those cases in which the patient's deranged behaviour caused considerable hardship to others—e.g., through violence (which was displayed by 63% of patients in this category), sexual deviation, callousness, paranoid accusations, and threats of suicide.

Where the patient's behaviour caused less serious hardship, the rating "moderate liability" was given, and patients whose symptoms, if noticeable at all, caused no obvious distress to others were rated "minimal liability". This estimate was influenced by the attitude of the other members of the household, some of whom found even slight psychotic symptoms very disconcerting, whereas others (especially certain mothers) showed extreme indulgence.

17% of the total sample were rated severe liability, 28% moderate liability, and 55% minimal or no liability. Many of the patients who caused distress to others (79% of those rated severe and 44% of those rated moderate liability) relapsed within the year.

The category severe liability included 16 patients who were discharged against medical advice, either after an escape *or at their relations'* behest, but proved too difficult to cope with in the home, as in the following example.

Case 1.—Discharged after his third admission for schizophrenia, which he had had for eleven years. Still profoundly disturbed, liable to attack his mother and step-father in sudden outbursts. These attacks were tolerated, but when he began to make sexual demands on his sister he was returned to hospital.

Among the 156 successes there were 36 patients (23%) who caused moderate hardship to others and 8 whose presence in the household caused severe hardship. In the latter group it was evident that the burden of a very disturbed patient had only been transferred from the hospital to the home. 4 of these patients lived with their parents, *3* with their wives, and 1 with a foster-sister.

At the other extreme, patients rated as minimal liability *tended to have a favourable outcome*, except for *24* men who went to live in Rowton Houses, Salvation Army hostels, or other institutions. 11 of these returned to hospital, for the most part of their own choice. These probably form part of the group of long-stay patients referred to in the Royal Commission report as "having reached the stage at which they could return home if they had a *reasonably good home* to go to."

It is in the intermediate category of patients presenting moderate liability that attitudes of persons in their immediate environment might especially be expected to influence the outcome. A typical example was the following.

Case 2.—Schizophrenic, aged 26, taken home against advice. Remained at home nearly two years although not well enough to work, often hallucinated, afraid to be left alone, and conspicuously strange in manner. "You could not take him out to meet people." Parents lived in a genteel suburb and were embarrassed by son's appearance, their social activities were much restricted while he was at home.

Discussion

Previous follow-up studies have emphasised the diminishing chances of recovery of patients whose stay in mental hospital is prolonged. Smith (1946) and Stringham (1952) reported a poor outcome for the discharged chronic psychotic. In contrast, the present study showed that 2 of 3 long-stay patients succeeded in remaining in the community for at least a year after discharge, and that 2 of 3 of these successes were maintaining a viable social adjustment. In contrast to the usual findings with early cases, the outcome bore little relation to the patients' ages, recorded diagnoses, or length of stay in hospital, it did, however, bear a significant relationship to the social group to which they returned and to their employment record.

It is no new discovery that it is sometimes inadvisable for schizophrenic patients to return to their own families, the point has been made in many of the standard textbooks of psychiatry, and it provides one of the arguments in favour of foster-homes. The present study, however, makes it possible to support the assertion with a substantial series of instances. Freeman and Simmons (1958), discussing the outcome of male psychotics discharged after a short stay in hospital, contrast the outcome of those who returned to conjugal and to parental settings and conclude that wives have higher expectations of performance in relation to the recovered patient than do parents. Patients are just as likely to fail in the conjugal setting, but if they survive they do so at a higher level of social functioning

The importance of employment as a preventive of relapse is emphasised by Cohen (1955), who showed that, when chronic schizophrenics left a Veterans' Hospital, their success in avoiding relapse was not related to the continuance of minor symptoms but was significantly related to their success in finding work, and that this, in turn, was related to the amount of vocational planning before the patients left hospital The present study suggests that employment is not only beneficial for the patient but also makes it easier for the household to tolerate a mentally handicapped member In this connection it may be noted that many of the patients who were unemployed were judged by the investigators to be capable of working. If they could have been offered sheltered employment pending their return to normal work, their chances of survival in the community would have increased

To help in finding jobs and suitable accommodation is a principal function of the psychiatric social worker It is no adverse criticism of them but rather a reflection of the volume of work which they have to undertake, that so few of these patients were able to profit from their services Nor were the patients the only ones who needed social-work help The assessment of "distress caused to others" revealed that in many cases the patient's household needed help in dealing with problems presented by his return "Community care" will not represent an advance in treatment if it means that a burden has merely been transferred from the hospital to the family As was shown some years ago for shock treatment (Feldman et al. 1947), it may be necessary to intensify the provision for aftercare so as to derive the full benefit of the new emphasis on extra-hospital treatment of the mentally disabled

Summary

A follow-up inquiry was completed with 229 of 240 patients discharged after more than two years' stay in a mental hospital

68% of these patients succeeded in remaining out of hospital for at least a year, and 66% of these were rated as showing either full or partial social adjustment

Successful outcome was associated with patients' clinical state on discharge, with their subsequent employment, and with the social group to which they went Patients staying with siblings or in lodgings did better than those staying with parents, with wives, or in large hostels

In this group of patients the outcome bore little relation to patients' age, recorded diagnosis, or length of stay in hospital

The social liability presented by these patients to their households was estimated.

The need for supportive social work with ex-patients and their families is pointed out

PSYCHIATRIC RESEARCH IN THE STATE OF ILLINOIS

J R SMYTHIES
M.A, M.D Cantab, M Sc. British Columbia, D.P.M
PSYCHIATRIST II AND PRINCIPAL INVESTIGATOR
GALESBURG STATE RESEARCH HOSPITAL, GALESBURG, ILLINOIS

In the past ten years an astonishing change has transformed the field of psychiatric research At one time this field was almost equally barren of ideas, workers, and money A few small groups kept up a brisk pioneering enterprise, but the massive support available to other fields of medical research was lacking This has now quite changed, and the ideas, the workers, and the money are accumulating at an ever-increasing rate The ideas are those fruitful hypotheses of the chemical basis of schizophrenia that are leading to so much biochemical, pharmacological, and physiological work on the ætiology of the psychoses[1] The new biochemical insights gained and the new drug therapies such as the group of phenothiazines have revolutionised psychiatry, as Dr Percival Bailey has recently proclaimed But the present article will be concerned with another aspect of this progress—the very essential one of the financial and administrative machinery that has made all this possible The increase in momentum of psychiatric research has been more noticeable in the United States than in England, and nowhere has this been so more than in the Department of Public Welfare, a branch of the State Government of the State of Illinois Psychiatric research in the United States is supported from four main sources—the great private Foundations, the Federal Government, the Armed Services, and the individual State Governments Each of these make contributions to the total, but this article will be concerned with just one part of one of these with which I am familiar

In 1949 the Legislature of the State of Illinois decided that the only way to combat the ever-rising costs of care of the mentally ill was to organise research in psychiatry A plan was devised whereby money paid to the State by the patients and the relatives of patients in the State psychiatric hospitals should be devoted to psychiatric research and training This money contributes towards a special Mental Health Fund which is devoted to six main projects (1) psychiatric research, (2) training of medical, nursing, and other professional staff, (3) mental health education of the general public, (4) community mental health services, (5) service improvement projects (i e, studies of the system designed to improve its efficiency), and (6) administrative costs of the other five projects (e g, the cost of collecting the money from relatives)

The fund runs on a biennial budget, and this for the years 1957–58 amounted to $24,000,000, of which some $7,000,000 came from the payment made by the patients and their families The portion of this devoted to psychiatric research and training during this two-year period was some $4,000,000, of which about half was devoted to research This fund is administered by a special body—The Psychiatric Training and Research Authority set up within the Department of Public Welfare with the advice of the Illinois Psychiatric Advisory Council to which members are appointed by the Governor and which meets once a month. It consists of the heads of the Department of Psychiatry of the Chicago medical schools, of the Michael Reese Hospital (a leading centre for psychosomatic medicine), and of the Institute for Psychoanalysis as well as Dr Otto L Bettag, the director of the Department of Public Welfare

---

[1] Smythies, J R. *Lancet*, Aug 9, 1958, p 308

The main centre of psychiatric research in Illinois is not set in Chicago as one might have expected but in Galesburg, a pleasant little town of some 30,000 inhabitants in Western Illinois The Galesburg State Research Hospital is one of the only five hospitals in North America that has been fully accredited by the American Psychiatric Association and is one of the most modern and up-to-date hospitals in existence It is built on the villa principle, and each villa holds 30–40 patients The research laboratory is directed by Dr Harold E Himwich, a ranking authority on the chemistry of the brain, and the work is devoted to studies of the biochemistry and pharmacology of the nervous system Important work has been done on the pharmacology of the reticular formation and of hallucinogenic and phenotropic drugs, on the biochemistry of maturation and ageing, on the chemistry of psychosis, the clinical evaluation of new drugs, and other related subjects

But I am dealing with administration rather than with the research itself, and it will interest British readers to learn that the research budget of the laboratory for funds devoted solely to salaries, equipment, and materials is $883,220 for the biennium, the significance of which I will return to below The State also supports at Elgin State Hospital a biochemical laboratory that operates on a budget of $148,000 with other sources of funds outside the State and two projects at Manteno State Hospital under Dr Nathaniel Aptner at a rate of $66,000 a year The Mental Health Fund also finances a large number of projects in the universities of the State The main one of these is the Illinois Neuropsychiatric Institute (a section of the University of Illinois) Here work is being carried out in neuropathology, on the tissue-culture of neurones, and on biochemical changes in schizophrenia Twelve other projects are being conducted in various branches of the University of Illinois bringing its yearly share to $350,000 The University of Chicago has two projects at $80,000, the Michael Reese one at $34,000, Chicago Medical School one at $23,000, and Loyola University one at $26,000 These projects cover child psychiatry fairly substantially as well as purely biological problems

In spite of this lavish outlay, income for the first few years of the projects has accumulated faster than it was spent, and these accumulated funds have been used to build two new psychiatric research hospitals in Chicago The Illinois State Psychiatric Institute is now complete at a cost of $9,000,000 and is truly a magnificent building It will be run by the Department of Public Welfare and staffed mainly by five services from the Chicago medical schools The second hospital will cost $5,500,000 and is a pædiatric hospital for mental defectives These two hospitals will undertake extensive research and training of psychiatrists

Now to devote some attention to the input side of the money flow—to use a cybernetic analogy The charges for inpatient care in the State hospitals are set by the Department of Public Welfare for each case after a careful consideration of the patient's financial resources and these charges vary from a maximum of $81 a month to nothing The patient or his family is free at any time to dispute these charges in the courts, although this is in fact very seldom done It should be remembered that here is no National Health Service of any kind in the United States, and so people expect to pay for the servi that they receive in hospitals

In conclusion it is interesting to note that the resear budget of the Galesburg State Research Hospital (sp wholly on salaries for research workers, goods, an equipment) is $441,600 a year The total expenditu from Government sources in the U K for the year 195 on psychiatric research came to £83,000[2] which i equivalent to $410,000 (counting £1=$5, the cost-o living equivalent)

The enlightened mental health research programme the State of Illinois is financed by those personally mo interested in the discovery of the cause and cure of ment illness—the patients themselves and their families— whereas the total cost of maintaining the patients is born by the State This bold scheme is already spreading in th States and has been adopted by Louisiana As it is much smaller and poorer State than Illinois its researc and training budget is only $350,000—which is never theless a respectable sum

I am most grateful to Dr Otto L Bettag, director of the Depart ment of Public Welfare, and to Dr Lester H Rudy, superintendent of the Galesburg State Research Hospital, for making available the facilities that have made this report possible

Medicine and the Law

Tale of Two Patients

A CORONER'S jury has returned a verdict of death by misadventure in a case in which the wrong patient was discharged from hospital[3]

A Mr Grange, who had been involved in a road accident, and who apparently had some deformity, was admitted to hospital at about 11 P M after being knocked down by a motor-car He was found by the casualty officer to be "moderately shocked" and was put to bed under observation An elderly man, also a road-accident case, was admitted the same evening, after treatment, his discharge was arranged provided that his own doctor was known so that a letter could be sent to him

The casualty officer went to bed, and was awakened at about 2 A M by his staff nurse She and another staff nurse apparently inquired if the crippled man could go home When the casualty officer did not answer, one of them added "the person under observation" The casualty officer then said that the man could go if he had a letter for his doctor

The casualty officer was awakened again at 6 A M and was told that a doctor had telephoned to say that he was returning a patient because he thought he was suffering from internal hæmorrhage It was then that the casualty officer discovered that Mr Grange and not the elderly man had been allowed to leave Mr Grange died a few hours later

At the inquest a consultant surgeon said that, ideally, the patient's record card should have been taken to the doctor "That is being wise after the event"

The coroner told the jury "It might seem to you that things have been rather lackadaisical but there is no evidence of negligence of a kind which is likely to lead to a charge of manslaughter" It would be wrong for them to word their verdict in a way that might show that they were trying to decide some question that could be settled in a civil court

The coroner also told the jury that he did not think it necessary for them to add anything to their verdict, as senior officials of the hospital were present "I feel that we can rely on the hospital, if there is need for tightening up to be done"

---

[2] *Hansard*, Jan 27, 1958, col 24 This figure is taken from a written report by the Minister of Health It includes £58,000 from Exchequer funds spent by the Medical Research Council and £25,000 spent within the National Health Service It does not include expenditure on research in universities and medical schools

Public Health

BRONCHITIS AND THE ACIDITY OF URBAN PRECIPITATION

EVILLE GORHAM
M Sc., Ph.D
ECOLOGIST,
FRESHWATER BIOLOGICAL ASSOCIATION, AMBLESIDE, WESTMORLAND

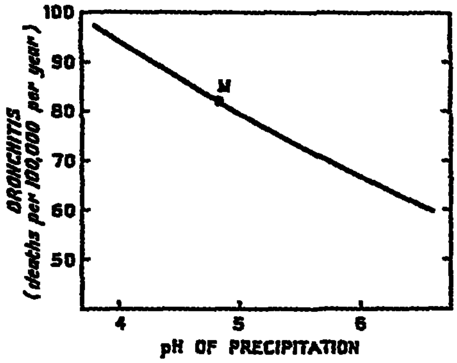
THE incidence of bronchitis is uncommonly high in Britain, especially in urban areas during winter, and it has been conjectured that air pollution is at least partly responsible. In this paper I report a correlation between bronchitis mortality and the acidity of urban precipitation

The mortality-rates for bronchitis were calculated from the Registrar General's annual statistical reviews for the whole populations of fifty-three county and Metropolitan boroughs in England, Scotland, and Wales over the five-year period 1950-54, and plotted on scatter diagrams versus air-pollution data from single stations and periods within these boroughs These latter data were extracted from table 8 of the 27th Report of the Department of Scientific and Industrial Research on the investigation of atmospheric pollution (1955), which provides figures for the monthly atmospheric deposit of tar, ash, other combustible matter and sulphate per unit area in urban districts, and also gives the pH of the precipitation Of all these, only the last two showed any obvious relationship with the bronchitis death-rates, and a more detailed statistical treatment was then carried out, using in this case averages of all the pH and sulphate values given for the winter months September to March in each of the fifty-three boroughs To obtain a more normal frequency distribution, and also a more linear regression, a logarithmic transformation of the bronchitis death-rates and of the sulphate deposits was employed.

The logarithmic correlation coefficient (r) for bronchitis and winter pH of precipitation amounted to −0·49 a value significant at the 1% level The corresponding coefficient for bronchitis mortality and winter sulphate deposit, which is no doubt related to the production of sulphur dioxide from fuel combustion, amounts to −0·32, a value significant only at the 5% level

To test further the above relationships, partial correlations of bronchitis mortality with the pH of winter precipitation and with the winter sulphate deposit were carried out, in order to eliminate the effects of any correlation between the two environmental variables Following this procedure, the coefficient of correlation (first-order) between bronchitis mortality and pH of winter precipitation fell only slightly to −0·45, a value still significant at the 1% level. In contrast, the correlation with sulphate deposit declined considerably, the first-order coefficient of −0·24 being no longer significant even at the 5% level. It is therefore unnecessary to consider this last correlation further

The partial regression equation relating bronchitis mortality (b, as deaths per 100,000 of population per year) to the acidity of winter precipitation (a, as pH) is $b = 192(0{\cdot}838)^a$ This relation is shown graphically in the chart, from which it may also be seen that the logarithmic average of the annual urban death-rate from bronchitis is 82 per 100,000 persons, or about 1·8 times the rural death-rate for the same period In those areas where rain pH is below 4, and hence strongly acid the death-rate reaches 100, while it is only about 60 in those urban areas with the least acid rainfall The rural death-rate for the same period is considerably lower even than this, at 46 annually per 100,000 of population, so acidity would not appear to be the only factor involved in the increased urban death rate, if in fact the acidity correlation is taken as truly causal While such an interpretation must of course be regarded with caution, it seems not unreasonable to infer that long-continued exposure to acid aerosols might increase the likelihood of bronchial inflammation In this connection it must be borne in mind that during dry weather the aerosol droplets will be considerably more acid than the ultimate raindrops in which they are precipitated, and may well exhibit pH values below 2 at times



The relation between bronchitis mortality and acidity of precipitation in urban areas. M gives the logarithmic mean death-rate.

Even in predominantly rural areas the rainfall may be quite strongly acid For instance, in the English Lake District rain pH averages less than 4·5, and goes below 4 on occasions, owing to atmospheric supply of sulphuric acid with easterly winds from the great industrial areas (Gorham 1958a) Surprisingly, however, in the industrial cities themselves hydrochloric acid seems likely to be the chief cause of low pH values (Gorham 1958b) The effects of both these strong mineral acids on bronchial tissues might well repay detailed investigation

I am much indebted to Mr David Driver for help with the calculations.

Strontium 90 and Malignant Disease

A report in the *New York Times* of Sept 20 refers to new work on the important question of whether or not there is a threshold level of ^{90}Sr in bone, below which no bone cancer or leukæmia is induced The work is that of M P Finkel at the Argonne National Laboratory in Lemont, Illinois, and it is described in detail in *Science*, in an issue which has not yet reached us ^{90}Sr was injected in varying doses into 810 mice, and the incidence of tumours and length of life in this group was compared with those of an uninjected control series According to the *New York Times*, the results suggested that no damage was done by small doses—in other words, there *was* a threshold in mice. From observations in cats and dogs, however, Miss Finkel estimates that ^{90}Sr is probably "seven to fourteen times more harmful to man than to mice, because of his greater size and other factors" Her conclusion is that the threshold for man is so much higher than present fallout levels that fallout is extremely unlikely to induce "even one bone tumor or one case of leukemia"

On the assumptions that no threshold exists and that weapon tests stop this year, the recent United Nations report[1] estimated that fallout radiation may produce 400 to 2000 cases of leukæmia a year Assuming a threshold of 400 rem, the U N Committee's figure for fallout leukæmia dropped to zero

Congresses

TROPICAL MEDICINE AND MALARIA

The Sixth International Congress of Tropical Medicine and Malaria was held in Lisbon on Sept 5–13 under the presidency of Dr J Fraga de Azevedo (Portugal), with Sir Philip Manson-Bahr (U K) as an honorary president The palatial new building of the Portuguese Institute of Tropical Medicine, which has had fifty-six years of vicissitudes since its inception, was ready just in time for this occasion

Acclimatisation to Heat

Sid Robinson (U S A) summarised physiological adaptations to heat as (*a*) improvement in efficiency of evaporative cooling and in sensitivity and capacity of the sweating mechanism, (*b*) increase of circulating blood-volume during exposure, accompanied by improvement in circulatory stability, and (*c*) dramatic improvement in temperature regulation so that by the 8th day of exposure, men may perform work in heat with no greater elevation of rectal temperature or metabolism than when they perform the same work in a cool environment

D E Bass (U S A), however, reported a recent finding of venoconstriction and reduction of blood-flow in the forearm during work in heat, occurring only on the 3rd and 4th days of exposure, and suggested that such venoconstriction might improve cardiovascular performance by maintaining functional blood-volume, this led him to reconsider the concept that cardiovascular improvement resulted from actual increase in basal blood-volume

W V Macfarlane (Australia) discussed human water economy in the heat, aldosterone, and several interesting seasonal differences in body responses to fluid loss In winter, for example, plasma-volume did not fall on the loss of 3 litres of sweat, nor did antidiuretic substance (A D S) appear in the plasma, in summer, plasma concentrated with the same sweat loss and A D S appeared

C S Leithead (U K) reported a significant fall in hæmatocrit and circulating protein levels in men on their 4th day of exposure to heat in Kuwait, and interpreted this as evidence of increase in circulating blood-volume by hæmodilution Prior to this, tilt-board and exercise tests had revealed cardiovascular instability of the subjects, but giddiness and syncope appeared only in those who had never before been in the tropics and to whom, therefore, all was strange—climate, environment, and customs

This possibly cerebral effect was emphasised by E M Glaser (U K), who observed that acclimatisation to heat depended partly on stored information which modified some heat-regulating responses and which resembled habituation and learning Subjective responses to warming were also modified during acclimatisation to heat, and it seemed possible that this was also due to a cerebral mechanism of habituation

Heat Tolerance

R. K Macpherson (U K) described "heat tolerance" as a simple title for a complex subject When a man exposed to heat collapsed, the limit of physical tolerance had obviously been reached and passed, but long before that stage the man's powers of perception, reason, and judgment were impaired and it was difficult to say when such deterioration began Tolerance was also to some extent *affective* in that there would always be a limit to the willing endurance of discomfort

H S Belding (U S A) mentioned at least eleven indices or scales of heat stress, including the heat stress index (H S I) recently proposed by Professor Hatch and himself[1] Before accounting for such variables as sex, age, degree of acclimatisation, it was first necessary to index valid in application to young, fit, and fully men Even then, the factors affecting heat stress were f able enough temperature of air, solid surroundings and ambient skin and vapour pressures, air speed, bod area and postural attitude, body-heat production, cl time of exposure Each factor required quantitative and deficiencies of the present H S I lay in misestimates circulatory strain imposed upon the subject, his skin ture, and the effects of clothing

The problem of whether men working in spaces radiant-heat load is severe (e g , at furnace doors) be or seminude should be one of concern to industrial officers Professor Belding believed that clothing reduced heat stress by blocking radiation and convection conceded that it might reduce evaporation from the skin argued that increased sweat production which wetted clothing and thus gave a larger total surface for would be compensatory

F N Craig (U S A) from a study of the phys state of subjects at the end of their tolerance-times (i e, time period elapsing before voluntary withdrawal environmental heat stress) concluded that the total heat in the body was the critical factor in tolerance of heat As heat storage was calculable from metabolic rate, resistance of clothing, and environmental humidity, he suggested that this was a method of heat tolerance

F H Bonjer (Netherlands) described experiments men working at a brick furnace In such situations, wished to know the maximum allowable working-time and minimum required rest period after exposure As the mini heat gain of the body was calculable for a given set of stances, the maximum allowable working time could be puted by dividing the presupposed maximum allowable gain (i e , 1°C rise in body-temperature, or 60 KCal in a of average size) by the minimum heat gain per unit of Derivation of minimum required rest period after exposure more complex and required further investigation

A R Lind (U K) said that in emergencies such rescue operations in coalmines, men were sometimes requ to work in environments too severe to fall within the range existing indices of heat stress He had found, however, that simple weighting of wet (×0 85) and dry (×0 15) bulb temperatures related climates of similar severity, and this formul proved effective for wide variations of energy expenditure and clothing worn, although the range of air-movement investigated was limited

D M Kerslake (U K) said that heat-stress effects due to small increases in absolute humidity were large when the skin was completely wet with sweat, and recent experiments showed that they were much smaller when evaporation of sweat was complete Effects on skin and mouth temperatures and on sweat-rate of resting subjects exposed to the same dry-bulb temperature (36°C) and air movement but to a wide range of absolute humidity accorded with expectation, and transition from partial to complete wetness of skin appeared to be abrupt and occurred at the expected level of absolute humidity (37 mm Hg)

Heat Illness

W P Stamm (U K) discussed the nomenclature and classification of heat illness The present W H O International Statistical Classification contained terms and concepts now archaic, and modifications proposed recently to the Climatic Physiology Committee of the Medical Research Council[2] were handicapped by an attempt to remain within existing W H O framework and coding

---

[1] Belding, H S , Hatch, T F *Heating Piping, and Air Conditioning*, 1955, 27 8, 111

[2] Weiner, J S , Horne, G O *Brit med J* 1958, i, 1533

Ellis (U K) read a paper by W S S Ladell (U K) idrotic heat exhaustion. This appeared to be funda- lly an endocrine disorder, as inability to retain salt ater accompanied anhidrosis, but failure of target responses was more likely than a central "stage of ex- on" because treatment with posterior pituitary extract xycortone acetate did not always help J P O'Brien alia), unable to attend, sent his belief that the disorder urely local in origin That facial hyperhidrosis was in the presence of anhidrosis elsewhere, and that the otic areas began to sweat if treated with anhydrous , were points which seemed to discount a hormonal

Guthrie (Kuwait) reported that heat illness, usually yperpyrexia and salt and water depletion syndromes, had h higher incidence among oil-tanker crews in the Persian than among those living and working ashore in Kuwait was due to lack of adequate air-cooling on shipboard, unsuitable habits of the sailors exposed. Some 20,000 lets, in eight languages, offering simple instructions in tion of heat illness had been issued to ships calling at it, this appeared to have had good effect, as marine cases sed there in the past three years numbered 222, 137, 3

P Crowden (U K) wished for a wider use of simple res to ensure health in the tropics Whitewashing the or of a corrugated-iron structure reduced the tem- re within When cotton mosquito nets, the meshes of were often occluded by fibrils, were applied to a hospital ur velocity over a possibly febrile patient was reduced to hth of its former level, but synthetic fibre mosquito net- ld not have such a major disadvantage Bright metallic es such as were afforded by aluminium foil had a high tivity and low emissivity for radiant heat, and were there- f value in heated industrial spaces

Toor (Israel) described experiments on two groups ly acclimatised men in the Dead Sea area[3]

Minard (U S.A) discussed prevention of heat casualties g Marine Corps recruits training at Parris Island, South lina. Changes in hot-weather training regulations for included adoption of a heat-stress index based eighted readings of dry-bulb, wet-bulb, and globe- nometer readings (wet-bulb,globe-temperature index of ou[4]) This index was chosen because of the simplicity of nstruments involved Use of the index to modify or restrict ing of recruits at certain levels of heat stress reduced heat lties from 12 4 per 10,000 in 1955 to 4 67 per 10,000 in

Nutrition

ne of the major problems of tropical countries is mal- tion in the young

Bassir (Nigeria) reported that the addition of soy- flour to the maternal diet had a beneficial effect on the position and volume of breast-milk

A Roels (Belgian Congo) had noted that in African hers on a staple diet the protein content of breast-milk during the first three months of lactation, that there correlation between the vitamin-A, carotene, and fat ent, and that there was no relation between content and me of breast milk

he changes in the blood picture in kwashiorkor in the four weeks under treatment were described by F Walt th Africa) Over 60% of children with megaloblastosis he bone-marrow were found to have kwashiorkor, and all cases responded within ninety-six hours after injection lic acid Sudden severe falls in hæmoglobin level had been rved in cases of kwashiorkor with sudden acute infection, pite a constantly rising serum-protein level

G Fuhrmann (Germany) described how his modification of the "arm-girth, depth-of-chest, and width-of-hip" index went some way to solve the difficulty of accurately assessing the state of nutrition

K Hill (U K) stated that infection or malnutrition or both are usually necessary for the development of veno-occlusive disease of the liver in response to ingestion of pyrrolizidine alkaloids

G Moretti (France) had studied the enlargement of the parotid gland in cases of alcoholic cirrhosis in France and of malnutrition in Guinea The histological picture in the two types was similar except that in the African cases interstitial fibrosis was a notable feature

H A P C Oomen (Netherlands) reported his studies in Indonesia on the response of the eye to malnutrition Besides xerophthalmia, retrobulbar neuritis was very common, and though vitamin A was very important the part played by protein and fat in the well-being of the eye must not be forgotten

An interesting condition of calcification of the pancreas in persons aged 15–30 in Indonesia was described by P J Zuidema (Netherlands) The patients required large amounts of insulin, had no steatorrhœa and no ketosis, but frequently had cataract Such cases seemed to be the result of malnutrition, the calcification of the pancreas having been preceded by fibrosis

Experimental aspects of tropical malnutrition was discussed by B S Platt (U K), who described his observations in pigs, in which a low-protein, low-carbohydrate diet produced a greatly different response to a low-protein intake high-carbohydrate diet

Trypanosomiasis

R B Heisch (Kenya) announced the successful isolation of *Trypanosoma rhodesiense* from the bush buck and its transmission to two human volunteers

Hæmoglobinopathies

C Trincão (Portugal) described the methods of identifying abnormal hæmoglobins The principal technique was that of electrophoresis, but there were many others—chromatography, determination of solubility, resistance to denaturation by alkali or by cold, oxygen saturation, aminoacid composition, number of NH_2 and SH endgroups, and antigenic properties Electrophoresis could be carried out at varying pH, by the open boundary technique, by zone electrophoresis on starch paste, starch gel, and agar, and by using various filter-papers or cellulose acetate as the supporting medium

H Lehmann (U K.) described the principal disorders The most severe were the homozygous conditions thalassæmia major and sickle-cell anæmia, milder were the heterozygous thalassæmia minor and the homozygous states for hæmoglobins C, D, and E Intermediary were mixed syndromes in which one gene for sickling and one for thalassæmia were inherited together or either of the two with that for another abnormal hæmoglobin. Additional stress such as pregnancy or infection could acerbate the less severe conditions so that the clinical condition resembled that of thalassæmia major or sickle-cell anæmia In the world distribution of these abnormalities sickle-cell hæmoglobin overlapped the distribution of thalassæmia and hæmoglobin C, and thalassæmia was also common in Asia, where it contributed to the high incidence in some regions of hæmoglobin-E/thalassæmia and in a not yet fully understood way to hæmoglobin-H disease

N C Ferreira (Portugal) said that the fœtal hæmoglobin in thalassæmia was indistinguishable from that in normal infants

R J Cabannes (Algiers) had found high incidences of hæmoglobin C in the High Volta, French West Africa In certain regions there, 17 2% of the people were hæmoglobin-C trait carriers (AC) and 1 3% were homozygotes (hæmoglobin-C

---

te *Lancet*, Sept 13, 1958, p 579

aglou C P Annual report no 9 to Commission on Environmental Hygiene, U S Armed Forces Epidemiological Board disease) The heterozygotes were completely normal, and the homozygotes were comparatively little affected, though there was some anæmia and occasional pains in the joints and the abdomen with gastrointestinal upsets There was some lability of the nervous system, which could be demonstrated in the encephalogram Hæmoglobin K was commoner in North Africa amongst the Kabyles and was found only occasionally in West Africa

Lie Injo Luan Eng (Indonesia), in a paper read on her behalf, said that both thalassæmia and hæmoglobin-E/thalassæmia were seen regularly in Indonesia These two were similar in their pleomorphism Whether splenectomy had any therapeutic value was as yet not decided Hæmoglobin-E disease was a *mild* hæmoglobinopathy, and the hæmoglobin-E trait caused no symptoms In some people the hæmoglobin-E trait was associated with microcythæmia and with an increased resistance of the red cells to osmotic lysis

A R **Nogueira** (Portugal) reported on the abnormal hæmoglobins of Portuguese East and West Africa In the East only sickling was found, but he could not confirm reports of some British workers who had described a very high incidence of sickling from Mozambique In the West, Angola showed sickling *only*, but in Portuguese Guinea 14 instances of hæmoglobin N and 11 of hæmoglobin K had been found among 9224 samples Some 20 samples containing a G-like hæmoglobin were still awaiting final identification

F B **Livingstone**, W **Zuelzer**, A R **Robinson**, and J V **Neel** (U S A) reported that some rare hæmoglobins—notably hæmoglobin N—were more frequent in Liberia than elsewhere In some regions of Liberia they had also found patients with classical thalassæmia and also a thalassæmia or thalassæmia-like condition where adults possessed high proportions of hæmoglobin F without their red cells showing the morphological features of thalassæmia

A **Woodruff** (U K) reported on the results of work where blood had been taken from patients with sickle-cell anæmia, "labelled" with radioactive chromium, and reinjected Following the fate of the radioactive cells it was found that there were two groups, one, amounting to about a third, was very short lived and disappeared in about four days, whereas the life-span of the remainder was only moderately reduced By scanning the body surface with a scintillation counter it was possible to show that most of the cell destruction took place in the liver

J P **Jonxis** (Holland) gave an account of the techniques employed in his laboratory for the recognition of the abnormal hæmoglobins In sheep there were differences between the oxygen-saturation curves of two adult variants So far no such differences had been noted in man Even fœtal hæmoglobin did not differ from adult hæmoglobin in that respect—provided that it had been freed from stroma and been thoroughly purified by dialysis Some hæmoglobinopathy-like conditions in which it had not been possible to find an abnormal hæmoglobin by current methods might turn out to be associated with abnormal oxygen affinity of the hæmoglobin

A I **Chernoff** (U S A) in a large survey, had found in North Carolina not only hæmoglobins S and C, but an appreciable number of samples with various "fast"-moving hæmoglobins Hæmoglobin D was present in 1% of American Negroes

L W **Diggs** (U S A) presented very full evidence that sickle-cell disease was a veno-occlusive disorder, the lesions occurring where blood was least oxygenated He demonstrated the development from infarct by sickled cells to necrotic lesion and to repair by organisation in virtually all organs and all parts of the body The spleen was most consistently affected Other characteristic injuries were aseptic necrosis of the head of the femur and occlusive lesions in the periphery of the eyeground The sickle-cell-trait carrier was not immune, he could suffer from splenic infarct when flying at high altitude in non-pressurised aircraft, and there was a specific *hæmaturia*

J C **White** and G H **Beaven** (U K) had compared t current methods of estimating fœtal hæmoglobin Equa good results were obtained with them all, provided the co centration was above 5–10% They improved the sensitivity fœtal-hæmoglobin estimation by combining the alkali d naturation of the non-F hæmoglobin with the measureme of hæmoglobin F in the residue Hæmoglobin F amounted 80 ± 10% at birth, and was less than 10% at four to months Traces could be found up to five years Values up 20% were found in sickle-cell anæmia and up to 90% thalassæmia *major* *Half of the cases of thalassæmia minor* of sickle-cell trait showed traces of fœtal hæmoglobin

J H **Walters** and H **Lehmann** (U K) had examin liver function in sickle-cell anæmia There was progress deterioration with increasing age This was reflected in a r of the serum thymol-turbidity units and in a fall of the pseud cholinesterase level Liver-biopsy specimens showed sinuso filled with a network of silver-staining organic material wh tended to form layers on the walls of the sinusoids

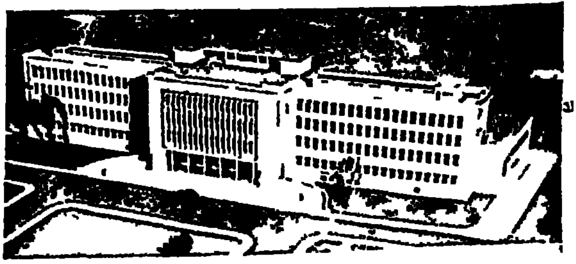
At a round-table discussion a resolution was prepared for t final plenary session of the congress

> "It is recognised that the hæmoglobin diseases present a m *health problem in the countries where they are found—most of th* tropical Millions of people are affected in Europe, Asia, Africa, a the Americas With the expected decrease of infectious diseases t importance of genetical disorders—amongst which the hæmogl binopathies are foremost—*will become greater rather than less* The encouragement is desirable of surveys of the distribution thalassæmia and of the abnormal hæmoglobins Though much h been done, there are still wide gaps in our knowledge Without su information planning of public-health measures will be handicapp With the rapid rate of discoveries of new hæmoglobins and n disorders a real risk arises that the nomenclature of these hæmoglobi *and the terminology of these disorders become confused* T gathering of workers interested in the hæmoglobinopathies hopes t sooner rather than later steps will be taken to arrive at internatio agreement As regards the terminology of clinical disorders cog sance is taken of the 'Recommendations' prepared by the Colo Medical Research Committee Working Party on Sickle-Cell Tr and Sickle-Cell Anæmia, London published in *The Lancet* a *British Medical Journal* on May 25, 1957"

INSTITUTE OF TROPICAL MEDICINE

The new home of the Institute of Tropical Medicine occupies commanding position near the Feira das Industrias Portugesas, the Avenada da India, on the banks of the Tagus

The white stone building is flanked by sculptured symbolic figure and in its wide approach stands a statue of Garcia de Orta, t Portuguese Hippocrates who published his great work on India 1563 Its six floors offer ample space for teaching and research The



two large air-conditioned amphitheatres, which can each seat 12 students, are equipped with head-phones and projection apparatus o all kinds The three laboratories each provide working space for 6 students and independent tables for each The institute has the following departments hygiene and climatology, entomology and helminthology, dermatology *and mycology*, and bacteriology and virology There is a special service for radioisotopes

A special number of the annals of the institute has been published to mark the occasion It gives a full history of tropical medicine i Portugal It describes the schools of Goa, India, Loanda, Angola, Lourenço Marques, Mozambique It shows the range of work o the institute's activities, which extend from Timor in the Indonesia Archipelago to the Cape Verde Islands

In England Now

A Running Commentary by Peripatetic Correspondents

SOCRATES ON MEDICAL EDUCATION*

Alcibiades Tell me, Socrates, how can we be sure that our ctors are well trained?

Socrates Do you think it right, Alcibiades, that we should r of a pudding that it is good or bad?

Alcibiades Certainly, Socrates

Socrates It must be possible then to distinguish a good dding from a bad one?

Alcibiades Of course it is, Socrates

Socrates And I suppose you would say that a good pudding ist have good ingredients?

Alcibiades That is so, Socrates

Socrates Tell me, Alcibiades, which ingredient do you think most important?

Alcibiades I think the flour is, for without the flour there ıld be no pudding

Socrates And whom do you consider the best judge of flour?

Alcibiades I suppose the farmer, who grows the wheat, can ıt tell which is the best flour

Socrates And would you say the miller also has this knowlge?

Alcibiades Yes, the miller also

Socrates So it would follow, would it not, that the farmer d the miller are amongst the best judges of what is a good dding?

Alcibiades It would seem so, Socrates

In like manner Socrates persuaded Glauco to say that the ultry-keeper must judge the eggs, and Agathon that the vinerd owner knew most about the raisins

Then Apollodorus broke in But Socrates, you have fortten the honey!

Socrates I was coming to the honey, Apollodorus, but tell why you think it important.

Apollodorus It gives sweetening and flavour to the whole idding, Socrates Why, half the pudding is the honey

Socrates That would surely mean putting a great deal of ney into a pudding!

Apollodorus I do not mean half by weight, but through its vasiveness honey is the other half of the pudding

Socrates How then would you judge the honey, Apollodorus? ould an Athenian who keeps bees be a suitable judge?

Apollodorus No indeed, Socrates, for he does others things sides keep bees The judge of honey must be a member of bee-keepers guild from Hymettus

Socrates Well, when you have judged the ingredients there still the mixing in the right proportions and the cooking at right temperature Would you include a cook amongst your idges?

Eryximachus Yes, Socrates, we must include a cook, but we ust be careful not to choose the one who cooked the pudding is well known that if a prize of 100 drachmæ were to be warded for the best pudding no cook would think his own udding worthy of less than 90 drachmæ

Socrates Where, then, would you find a cook to judge your udding?

Eryximachus If it is an Athenian pudding, to be on the safe ide you must choose a cook from Sparta

Socrates But what will happen if the Spartans do not like the ame kind of pudding as the Athenians? And do you think, lcibiades, that all your judges will agree about the pudding? r will the farmer, perhaps, say that his good flour has been poiled in the mixing, and the raisin-grower that there is too uch honey?

Then, turning to a boy who was sitting at his feet, Socrates nd Boy, you have heard what Alcibiades and the others have id. How would you decide whether a pudding is good or ad?

Boy I would eat it, Socrates!

For a congress on tropical medicine there could hardly be a more appropriate venue than Lisbon with its long history of adventure and exploration The hospitable Portuguese had rushed ahead with their new institute of tropical medicine, so that we could meet within its walls, though some of the rooms had not been finished Indeed when we first arrived workmen were surging around with buckets of cement The film room, which hardly existed on Sept 4, was complete and in working order on the morning of Sept 5 The main staircase had only been put in place four days before, and a gang of a thousand navvies worked all night to get the building ready for the congress

Behind the information desks sat Portuguese ladies who, though sometimes a bit puzzled, were always most helpful, and we soon came to learn why these people are acknowledged as the kindest and most considerate in the world. Typical of their friendly and charming hospitality were the attractive stamps issued to commemorate the Congress, which showed gaily coloured birds, flowers, insects, and mammals from the Portuguese tropical possessions At our meetings, social and scientific alike, everyone was pleased to meet everyone else, had something to impart, or questions to ask It may well be that we all had diverse blood-groups or harboured different brands of hæmoglobin, but the antigen of good will was common to all

* * *

A student of art learns to look for the characteristic touches of the master He knows that certain themes recur frequently—perhaps the pattern of light thrown by a candle, or the gables of a house viewed from a characteristic angle The same is true in science, and when this year I began to review half a century of progress in cardiac physiology I found that I recognised not only the style and mannerisms of some authors over the years, but sometimes also their hopes, their disappointments, and their regrets There is a poignancy in the way they return to an idea or concept, born of some ancient intellectual anguish but fated by hard facts to die It is almost as if they hope yet to detect life where there is none

The ancient journals, too, have a strange, nostalgic fascination. It is a privilege to lift the veil and listen, even if rather indistinctly, to men like August Krogh or Lindhard or Yandell Henderson, and how interesting it is to find that the views some of my older contemporaries express today found origin in ideas and concepts that they lived with, as only a scientist worrying out an idea can live, perhaps thirty years ago

* * *

My partner, who has only been two years in general practice, remarked the other day that really important statements by patients or their relations are often made on the doorstep on departure

My mind must have registered this too, without having put it into words, for it at once accepted the truth of the observation If I needed confirmation it came at once The next day as I was leaving the house of a man with depression and dyspepsia, who refused to own up to any worries or reasons for nervous tension, a married daughter saw me to the door and literally on the doorstep said, "You know, my sister wants to get engaged, but father so dislikes the idea of losing his youngest daughter that he won't even meet the young man."

The incident that had struck my partner so forcibly was his visit to a child with the mildest of sore throats As he was leaving the mother said, "By the way, doctor, my husband is coughing up blood, but he won't tell you himself"

* * *

A colleague practising in a Yorkshire mining town describes his most embarrassing moment Called in to give a supporting certificate for cremation, he did his duties quietly and speedily and expected that the undertaker would be equally circumspect, and would forward the prescribed fee later on

A few days later he stood to attention in the High Street as a funeral procession crawled by Suddenly the leading vehicle swerved across to where he stood and a hand poked out towards him "Your £2, doctor—saves a stamp," said the top-hatted and black-coated driver, who then resumed his place at the head of the dignified procession

*The first meeting of the Association for the Study of Medical Education is being held in London this week.

Letters to the Editor

THYMECTOMY AND MYASTHENIA GRAVIS

SIR,—There are many arguments against the likelihood of thymectomy benefiting sufferers from myasthenia gravis The only justification for attempting the surgical experiment was the enlargement of the gland in some patients and the presence of a " thymoma " in a number of others It has to be admitted, however, that a majority of patients have a thymus that is normal in every respect, and, again, a thymoma does not necessarily lead to myasthenia Removal of the thymus is followed by no *symptom whatever, no recognisable syndrome of hypo*-thymism This suggests surely that the function of the thymus, if any, is duplicated by other organs and that this gland is comparable in this respect to the spleen rather than to any known endocrine gland

When we come to the results of thymectomy, recently assessed by Simpson [1] and discussed in your excellent leading article of Sept 6, we find some very puzzling features The operation benefits women, but probably not men The worse results are to be expected when the most abnormal glands, the thymomas, are removed, although an excellent result is sometimes seen in this category of patients and indeed often follows removal of apparently normal glands The chances for the myasthenic to remain in status quo, operation or no operation, are about the same If men, children, and the bearers of tumours are excluded and assessment is focused on a special class, women between 16 and 35 years old, then we find a distinct advantage for surgery

My knowledge of the statistical method does not allow me to judge how far it is fair to separate and select groups of patients in this way Assuming the favourable response of some young female patients to be proven, I would like to refer again to a suggestion I made some years ago [2] I said then, " Can it be that myasthenia gravis is a label covering a number of disorders of the myoneural junction ? Every functional unit of the neuromuscular system has its own varied pathology Is it not, a priori, likely that the myoneural junction can be impeded in more ways than we know ? "

Suppose that an enterprising surgeon, fifty years ago shall we say, had decided for splenectomy in every obscure case of anæmia, as this organ was often known to be enlarged, would he not have had some remarkable results —for instance, in a group of young subjects with a familial incidence of anæmia ?

London, W 1 L P E LAURENT

THE NATURE OF THE INSULIN-ANTAGONIST ASSOCIATED WITH PLASMA-ALBUMIN

SIR,—We have recently shown that the inhibitor of insulin in the plasma of diabetic patients is associated with the albumin fraction Furthermore it was shown that albumin from normal subjects also has an inhibitory action [3] These studies gave no indication of whether such an inhibitory activity was due to the albumin per se or was due to a substance associated with it We now wish to present evidence that the latter is the case

Effect of Hypophysectomy

Three hypophysectomised patients have been studied Two of the patients had carcinomatosis and had their pituitary *ablated by transnasal implants of yttrium-90* into the sella turcica These patients were cortisone-dependent The third patient was diabetic and the pituitary gland was removed by surgery, which was easy and complete Albumin was prepared by the trichloroacetic-acid/ethanol method from the plasma of these patients and tested for insulin antagonism by the rat-diaphragm technique as described in our last paper [3] The plasma-albumin fractions from all these patients had no demonstrable antagonistic activity The albumin fraction in each case was tested at least twice The results which have been taken together are shown in the accompanying table In one case it was possible to determine the activity of the albumin fraction before operation and as expected this fraction was inhibitory

ACTION OF ALBUMIN FROM NORMAL, HYPOPHYSECTOMISED, DIABETIC SUBJECTS

Fraction	Mean glucose uptake above basal ± standard error of the mean (mg per 100 ml per 10 mg diaphragm)	
	Buffer + 1000 microunits per ml insulin	Fraction in buffer + 1000 microunits per ml insulin
Normal albumin (3 5–5 5%)	11 43 ± 0 62 (6)	0 50 ± 0 48% (6)
Hypox albumin* (4%)	11 85 ± 0 68 (8)	11·43 ± 0 80 (8)
Diabetic albumin (1 25%)	12 32 ± 1 04 (4)	3 55 ± 0 67 (4)
Diabetic albumin through column (1 25%)	*13 12 ± 0 65* (6)	*12 58 + 1 28* (6)

No of observations in parentheses

*Hypox albumin represents albumin isolated from the plasma of hypophysectomised patients

Removal of Activity on Columns of Cellulose

Albumin from diabetic patients (300 mg) was prepared, with the activity previously described,[3] dissolved in 4 ml of borate-phosphate buffer, and passed through a column (40 cm × 1 5 cm) of cellulose [4] The protein was eluted with buffer and a total of 150 ml of buffer was collected, the eluent extensively dialysed and the protein freeze dried When the activity of this protein, which was electrophoretically identical with albumin, was tested, the original activity against insulin was found to have been removed by passage through the column The results are shown in the table A similar result was obtained when 750 mg of normal albumin was passed through a column under similar conditions

Together, both these lines of evidence indicate that the activity of the albumin fraction from normal subjects and diabetic patients against insulin is not due to albumin per se The results of hypophysectomy indicate that the antagonistic activity is related, possibly indirectly, to the pituitary gland This gland may not be solely responsible, however, as is suggested from studies on experimental diabetes in animals Thus in depancreatised cats the presence of insulin antagonism in the plasma is dependent both on the presence of the pituitary gland and on adrenalcortical steroids [5] These results are in accord with those of Luft et al [6], who showed that the insulin requirements of diabetics who had been subjected to hypophysectomy fell as the result of the operation

We should like to thank Prof Russell Fraser and Dr J D N Nabarro for allowing us to study patients under their care, the Medical Research Council for a grant for scientific assistance, and Boots Pure Drug Company for supplies of recrystallised insulin

SKIN TRANSPLANTATION IMMUNITY IN RELATION TO HYPERSENSITIVITY

SIR,—Reading, with appreciation, the preliminary unication of Sept 13 by Professor Medawar and colleagues, I was left uncertain as to the nature of the terial obtained from the cells expressed from the phoid tissue of the recipient animal and injected in " direct reaction "—presumably mitochondria and osomes (R N A, granules), amongst other things

Professor Medawar at one time produced evidence ch indicated that there were tissue antigens in cell clei On general principle, it seems improbable that ue antigens or, to use Loeb's more descriptive term, erentials are the exclusive property of any particular extract or fraction More likely it is an attribute pervading all living macromolecular systems in the higher animal form and resides in characteristic molecular configurations The proteins, with a choice of over twenty aminoacids offering an infinite number of positions all the possible side-groups and linkages, could provide a sufficient range of molecular pattern for all tissues, viduals and species One wonders, therefore, if borate procedures and processing of living tissue adds anything to the problem of homograft reaction

SPHINCTER AND HIATUS

SIR,—An interesting aspect of the hiatus-hernia problem, so far not mentioned in your review of this fascinating subject, is whether or not so-called " sliding " hiatus hernias commonly slide

Belsey [1] has stated that they rarely slide to and fro through the hiatus, the radiological appearances being an illusion However, so long as it is generally accepted that a hernia may come and go spontaneously, the radiologist has an excuse for not demonstrating the lesion regularly when it is present, and moreover will tend to be preoccupied with manœuvres designed to promote reflux and/or herniation It is a common experience that repeated barium examinations are at present necessary in a proportion of cases

Rejecting this assumption immediately puts the radiologist on his mettle to improve the present unreliable technique In this respect the image intensifier offers hope for the future, with its use gastric-type mucosal detail may often be clearly seen above the diaphragm as the barium bolus passes, even in the erect position

Supposing that the hernial pouch is permanently fixed above the diaphragm and that the pressure within it approximates to that within the intra-abdominal stomach,[2] then support for the action of the external mechanisms acting at the hiatus in preventing reflux into the pouch during barium-meal examination, is provided by the following simple experiment

If a baby's feeding-bottle is inverted with the neck of the teat partially constricted (by compression or angulation), then the bulb will not fill completely with fluid because an air-bubble is present In the case of a hiatus hernia, this mechanism would probably act as a complete or partial air lock, the air being prevented from escaping upwards by the alleged internal sphincter or by a more diffuse contraction of the lower œsophagus, as mentioned previously [3] Complete occlusion of the neck of the hernia at the hiatus would be unnecessary, which would account for the rather unimpressive pressure changes found here

Belching would tend to lose the air and so promote reflux Donnelly [4] has related the formation of a hiatus hernia and reflux symptoms to this habit

BREAKING UP THE MENTAL HOSPITAL

SIR,—Although broadly agreeing with the views expressed by Dr Russell Barton (Sept 13), we feel that the topic is of such importance that it deserves further ventilation

Anybody who studies the history of psychiatry will find that from time to time during the last 100 years the same ideas on treatment have been dressed up in new clothes and put forward as a sure solution of the problems confronting mental hospitals This applies particularly in the field of *administrative* psychiatry where we now hear repeated pleas for the doors to be thrown open and the patients discharged to the tender and loving care of their relatives We also find a resurgence of the idea of community care, domiciliary treatment, and indeed complete abolition of the mental hospital

With the *medical* problem of psychiatry in its present state of flux, it is as well to view any of these new advances with a critical eye For example, nowadays the old concept of the hospital farm, where chronic patients could work, is considered outmoded and many hospital farms have been closed as uneconomic This idea has now been replaced by the plea for factories to be established in mental hospitals Are they to be more economical ? Some years ago large observation wards attached to general hospitals were instituted as an administrative solution to many problems in industrial cities such as Glasgow and Manchester Today this idea is discredited because these wards have failed to cope with the disposal of chronic cases Nevertheless, psychiatric departments in the general hospitals are suggested as a panacea against institutionalisation by some reformers The situation would not seem to be very dissimilar to that which prevailed in the treatment of tuberculosis before the advent of modern effective chemotherapy Some saw the solution in extensive village settlements, others through the provision for outpatient dispensaries, &c , in fact, the real advance has had to wait the advent of an effective medical rather than administrative treatment Administrative changes in psychiatry are required and may indeed be helpful, but we should like to make a plea for a degree of self-criticism which is not often apparent in those who conduct these so-called new experiments

We disagree with the views expressed in Dr Barton's article about institutional " neuroses " The features of apathy and indolence so often seen in chronic schizophrenics are essentially a product of the disease itself and, like aggression and hostility, not infrequently seen in schizophrenics who have lived outside a hospital all their lives, as we tried to demonstrate in our description of the chronic patient in India [5]

The enthusiastic and sometimes incautious discharge policy of some hospitals can indeed have tragic repercussions on the family

A case recently seen by one of us had passed through the hands of a mental hospital near London where a man in his fifties had been under care and treatment for the past ten years The hospital discovered that the patient had a sister in her seventies living near Birmingham and wrote to her that the patient was now well and was to be discharged under her care, no other preparations for the transfer were made The results were disastrous, the still psychotic patient nearly drove his sister to a breakdown and had to go into hospital in Birmingham This case is by no means an isolated example, and we frankly admit that we have seen equally bad effects on the family of some of our own patients we have attempted to discharge from hospital

Psychiatrists battling with a human problem of the greatest practical difficulty are certainly not immune from self-deception, but neither are experts in social medicine, nor our Great Planners and Medical Politicians A lack of critical evaluation of what we are trying to do often leads to an overactivity in the wrong direction and to a repetition of past errors

Uffculme Clinic,
Moseley, Birmingham

W Mayer-Gross
J A Harrington

Sir,—*The letter from Dr Russell Barton raises a* number of relevant questions

We know that some of our discharged patients have entered other hospitals, just as we admit patients who have been treated elsewhere Nevertheless, it is our impression that more patients move into our area than out of it This impression is strengthened by our social worker's reports and is in keeping with the fact that schizophrenic patients tend to be found in excess in the central areas of towns [1,2]

I am indebted to Dr Walk of Cane Hill Hospital, who has allowed me to see some figures he has collected from the Coroner's courts of South London These show that in 1956 and 1957 the number of ex-patients from Banstead who committed suicide was less than half of that for the other comparable hospitals

Contrary to Dr Barton's statement, we do not know of any mental hospital which is willing to take patients from our area Moreover, we have had referred to this hospital a number of patients from outside our area They were referred to us because of our policy of active treatment in an optimistic atmosphere

We are, of course, particularly concerned that discharged patients should not cause distress in their homes Apart from a general awareness of this risk, we have had a research scheme running for nearly three years, which is concerned with the social problems of schizophrenic mothers This group was chosen because it was thought it would highlight the problems of patients returning to the community It is apparent that all these patients have difficulties on leaving hospital—sometimes severe In general however, once overt symptoms have been treated, the longer the patient is away from home, the greater the difficulties the whole family will experience when attempts are made to re-unite them Once the optimal time has passed, families tend to organise their lives without the absent member

I entirely agree that institutional neurosis can develop in small wards as readily as in large, and the most important factor in curing this condition is the spirit which animates the staff It is difficult to see how a mental hospital can provide full after-care facilities without becoming unwieldy I would agree with Dr Barton however if he means that such facilities in the community should be supervised from the mental hospital

INDUSTRIAL MEDICINE AND GENERAL PRACTICE

Sir,—I should like to support Dr Keatinge (Sept in questioning Lord Taylor's contention that "a part of industrial medicine is neither more nor less general practice" The latter is freely assumed by people to be the only form of medical activity (other hospital work) undertaken by doctors, and when eminent authority emphasises this feature, it mak increasingly difficult for industrial medical officers to suade managements and employees that this is not case

In discussing broad issues generalisations are a sary evil, but I think few will disagree with the stat that the general practitioner mainly directs his effor the detection and treatment of disease while the medical officer is mainly concerned with the *relatior* between disease (or disability) and occupation relationship may find expression in three ways

(1) *Causation* disease or disability directly of origin

(2) *Aggravation* where conditions of work make wor disease or disability already present

(3) *Interference* where the disease or disablement feres with the ability of the employee to do his work

These aspects of the relationship between disease occupation may appear singly or together Whatever is case, the efforts of the industrial medical officer are directe removing, ameliorating, or otherwise adjusting the rel Ideally the relationship should exist in theory only, preventative medicine truly would have been done

If this simple conception of an industrial officer is kept in mind then there will be no confusio to whether he "practises generally"

Before I am attacked on all sides I should like to that the provision of emergency treatment for accid and illness is a vital part of his work but it should in way be regarded as the paramount reason for his existe in industry

TRIALS OF CONTRACEPTIVES

Sir,—This Council is trying to organise clinical tr to test the efficacy of existing methods of contracepti We are also hoping to try modifications of these meth and ultimately, we hope, entirely new methods will tested in the same way

To establish any new method of contraception ne volunteers who are willing to run a reasonable risk becoming pregnant, and who are also likely to be fert We have in fact two groups of trials running at present

Group 1, in which the volunteers use the method for fr 3 to 12 months and then prove both its effectiveness and th fertility by becoming pregnant, and group 2, in which vol teers use a method for about a year, being prepared to run risk of its failing but not being prepared to undertake pregnan There is also a third trial in which patients are medically se and examined at a special clinic session in London Grou and 2 patients are not seen unless the patient-volunt specifically wants to be seen

In view of our lack of accurate figures about t effectiveness of modern contraceptive methods a because of the importance of this problem both individual families and to world population trends we f that the trials are of vital importance

If any of your readers can put us in touch with volunteers who should write to the medical secretary at this address) e would be most grateful

HÆMORRHAGIC PLEURAL EFFUSION AS A MANIFESTATION OF SCURVY

SIR,—Dr Rozner and Dr Lloyd (Aug 23), in their teresting article on scurvy, quote Lind (1753) for an early description of pleural involvement I should like to call attention to Jacques Cartier's *Brief Recit* of 1545 in which he describes the postmortem findings of a case of scurvy in Canada in the year 1535

> "Because of our ignorance of the disease, the captain had the body opened to obtain whatever knowledge of it might help to preserve the rest of us if possible The heart was found white and wrinkled, with nearly two quarts of reddish, date-coloured water about it The liver was healthy but the lungs were all blackened and mortified and all the blood had collected above the heart, for when the body was cut open there issued from above the heart a large amount of dark, putrified blood The spleen, for two finger breadths near the backbone, was likewise a little affected, as if it had been rubbed on a rough stone These facts having been noted, one thigh was cut open and found very black outside but with fairly healthy flesh inside" (From the translation of Prof Jean L Launay)

Charles E Frost & Co,
Montreal

J M. PARKER
Pharmacologist.

CONTROL OF THE COMMON COLD

SIR,—Over a period of years, it was noted that quite unexpectedly good results were being given by prophylactic autogenous vaccines in the prevention of the common cold It seemed reasonable to assume that the function of the virus was essentially that of a starting handle, most of the later and debilitating symptoms being due to the patient's own nasopharyngeal bacteria which became out of hand as a result of the general depression due to the virus [1]

If so, a similar result should be obtainable by short-term local antibiotic therapy at the start of the symptoms, thus depressing the activity of the bacteria to correspond to the general depression of the patient A series of experiments was therefore carried out during the winter of 1956–57 The result confirmed expectations, in that use of the appropriate antibiotic at the onset considerably reduced the number of fully developed colds [2]

During the winter of 1957–58, a further trial was made on exactly the same lines as that of the previous winter, essentially as a check to ensure that the highly promising results achieved were not due to chance in any way The results are given in the accompanying table

The proportion of volunteers with prodromal symptoms who went on to a full cold was again much lower in the treated than in the control group As in the previous series, lateness in reporting prodromal stages proved disadvantageous, but this trial was intended to be a practical one and the figures therefore include all comers

From October, 1957, until May, 1958, 1120 volunteers were divided into two groups Of these, 838 received short-term antibiotic treatment when they felt a cold beginning, and 282 received an inert tablet In the treated group, prodromal stages numbered 304 (36 3%) of which 52 (17 1%) went on to full colds In the control group, the prodromal stages numbered 121 (42 8%) of which 64 (52 9%) went on to full colds—i e, 6 2 colds per 100 volunteers in the treated and 22 7 per 100 in the control group

Allowing for the fact that latecomers (i e., those reporting prodromal stages after a day or two) were accepted in 1957–58 and largely refused in 1956–57, these figures strongly support the findings of the previous year—4 colds per 100 in the treated and 26 per 100 in the controls For 304 volunteers where such assessment was possible the figure for 1957–58 worked out at 4 8%

The fact that the findings during 1957–58 show such a strong resemblance to those of 1956–57 is evidence that the conclusions put forward, and probably the assumption on which they are based, are correct In that case, the following points arise

(1) *Chronic cold sufferers* —The method of choice here is the autogenous vaccine, giving active immunity A short course of minimal oral antibiotic may if necessary be given to prevent development beyond the prodromal (virus) stage, but this should not be necessary once immunity has developed. A sensitivity test can be recorded when the vaccine is made in case it is required Incidentally, such patients as have had two courses of vaccine appear to have developed a lasting immunity, none ever having been given a third

(2) *The "casual" cold* —This does not warrant a vaccine and should respond to oral antibiotics on the lines indicated In industry, where a medical centre is available, sensitivities can easily be recorded in the early autumn, for use throughout the ensuing winter There is, of course, nothing to prevent

NUMBER OF VOLUNTEERS AND INCIDENTS IN EACH GROUP

[2] Ritchie, J M *ibid* p 618

practitioners doing the same with patients, but as these do not usually report at the beginning of a cold, the early opportunity is apt to be missed It has been found that, although there is a considerable degree of constancy in the mouth flora, it is better to repeat the sensitivity test each autumn

(3) *Influenza* —Many practitioners have noticed that treating some early cases of influenza with systemic antibiotics, on purely empirical grounds, appears to have reduced the incidence and severity of complications It is perfectly logical to assume that, if the cold virus is essentially a starting-handle, the influenza virus may be the same, albeit on a different scale The continued prophylactic use of systemic antibiotics may lead to the production of resistant bacteria and is therefore to be condemned, but their administration for a few days in an emergency like an imminent attack of influenza is open to no such objection As the result of a sensitivity test can be read after overnight incubation, there is no reason why the antibiotic appropriate to the patient's nasopharyngeal flora should not be used in an attempt to reduce the effects of bacterial invasion, even in cases of influenza

HÆMORRHAGIC LESIONS DUE TO STAPHYLOCOCCAL TOXIN

Sir,—The production of hæmorrhagic consolidation of the lungs, in mice, using filtrates of staphylococcal cultures, reported by Professor Ogasawara and Dr Tanaka [1], is an important observation The experiments reinforce the suggestion that fatal hæmorrhagic staphylococcal pneumonia, in man, is due to the production of staphylococcal toxin in the colonised lungs [2] Furthermore they re-emphasise that the rapidly lethal effect of staphylococcal toxin in experimental animals can be prevented by antitoxin, we hope this will encourage further trials of the treatment of acute staphylococcal toxæmia, in man, with staphylococcal antitoxin [3]

It might, however, be unwise to risk aggravating the characteristic systemic hypotension of staphylococcal toxæmia by the use of tetra-ethyl ammonium compounds or by chlorpromazine until there is further evidence of the efficacy of these drugs in protecting the pulmonary circulation from the acute pressor effects of staphylococcal toxin [4]

COLOUR INDEX IN NORMAL SUBJECTS

Sir,—Dr Pooley (Sept 13) gives values for the colour-index to the nearest 0 01 Such supposed accuracy is surely without meaning, for to be able to estimate the colour-index to within a range of 0 01 the hæmoglobin must be estimated to within ±0 25%, and the red cells to within ±12,500 per c mm

Even the more rational calculation within 0 05 requires a hæmoglobin ±1 25% and red cells ±62,500 per c mm —an accuracy beyond that of a routine hospital laboratory

Briggs and Allington, using the M R C photometer, found a standard deviation of 4 5% for successive hæmoglobin estimations on the same subject, and I have seen a teaching hospital laboratory vary by as much as 10%

I therefore doubt whether there is much practical value in reporting the colour-index to a second decimal place, using laboratory methods at present available

CHILDREN IN HOSPITAL

Sir,—It is difficult to criticise constructively the letter of Mr Herzog in your issue of Sept 6, as there so much with which a psychiatrist can agree I am sure he is right when he implies that patients over five years, and certainly those over eight years of age, can do with weekly or even less frequent visiting This is especially true when the community atmosphere is highly developed and when all the adults surrounding the children are able make good and happy relationships that are warm and permissive, not cold and punitive, as still happens in some children's wards

It is, however, one of the disadvantages of boarding schools that they weaken family relationships, at least in the pre-adolescent It is imperative that we constantly remember that family loyalty is something far more precious and important than group or national loyalty

With regard to the under fives, and especially to those of two and three years of age, frequent and if possible daily visiting is vital to the proper development of their personality and emotional stability One recognises that at times this may be very difficult and require great sacrifice on the part of parents, and that in some cases it is impossible However, it is our duty to see that parents who *say* they cannot visit frequently are, in fact, not unaware of the intense suffering of small children separated from their parents They should be helped to be made aware of the emotional needs of those small children and then perhaps they will realise that making tea for their husbands coming home from work is not in itself a good reason for staying away Any husband worth his salt can get his own evening meal

Of course, it is not just the frequent contact with parent and child that is important but the depth and quality of their unconscious non-verbal relationship This cannot, of course, be produced by ministerial directives on visiting Where it is deficient it can only be produced by analytically orientated group or individual discussions with parents Sometimes, of course, so malignant are the unconscious forces in a mother's personality that this happy relationship can never be produced

Would not Mr Herzog agree that the child in the film *A Two-year-old Goes to Hospital* suffered? Would he not agree that the clinging and demanding behaviour after that child returned home is at the very least distressing to parent and child? Surely it is our duty to minimise all suffering to the utmost of our limits For those who have eyes to see the film is quite conclusive A recent letter in the *Manchester Guardian* clearly demonstrated the after-effects of a prolonged stay in orthopædic hospitals, which were in essence a permanent and more severe form of those demonstrated by the film

The remark that disturbed me most in Mr Herzog's letter was that "crippled children stand out because of their quiet, non-complaining behaviour" By writing such a statement, he has unwittingly vindicated the work of Dr Bowlby and others Quiet passivity is the depressive picture seen in those who have suffered severely from prolonged emotional deprivation and is particularly seen in many displaced persons who have for years been emotionally starved in concentration camps, a sign therefore of serious maladjustment rather than good adjustment

Might I suggest that Mr Herzog and those who think like him could perhaps find time to study more closely with their psychiatric colleagues the sometimes hidden and subtle effects of hospitalisation

Carlton Hayes Hospital,
Narborough, nr Leicester
H B Kidd

Sir,—I am delighted to read that hospitals are not so bad for children after all I congratulate Miss Stephen and Dr Whatley (Sept 20) on their most enlightened approach to this question

---

[1] *Lancet*, Sept 13, 1958, p 589
[2] Gresham, G A, Gleeson-White, M H *ibid* 1957, i, 651
[3] Gresham, G A *Brit J clin Pract* 1958, 12, 247
[4] Burnet, F M, Kellaway C H *Med J Aust* 1930, ii, 295

I suppose we are an enlightened isolation hospital in that daily visiting of children is allowed, together with extra visiting as indicated

Personally I have noted little difference in the behaviour of children. The majority settle down as they always did A few fret and fume, but nine times out of ten they are nly children of elderly or anxious parents

As Miss Stephen and Dr Whatley say, some have actually benefited morally and psychologically from their stay, in particular backward children and those from homes where there is parental discord

Those that are discharged against medical advice do not amount to more than 0 01% of all admissions

Ilford Isolation Hospital,
Chadwell Heath, Essex.

Notes and News

AN ANATOMICAL LANDMARK

IT might be thought that when a new book is described by a reviewer as "not wanted", "low", and "unscientific in tone", it could have little hope of success And when its publisher goes out of business and its young author dies soon after preparing a second edition, the work must surely disappear Yet Mr Henry Gray's *Anatomy*, which suffered this vile concatenation of events, has survived, and today it prospers increasingly, as Mr William Longman was able to relate at a dinner given in Stationers' Hall, London, on Sept 18 to celebrate the centenary of its first appearance Prof T B Johnston, who has seen "Gray" through nine editions since 1930, ruefully admitted that fifty-seven years ago, when he traded his "Liddell and Scott" for "Gray", he felt at first that he had made a bad bargain. Anyone buying the centenary edition, though he must dig deep in his pocket, is less likely to be seized with regret than with gratitude to Professor Johnston and his two associates, Professor D V Davies and Professor Francis Davies, for keeping their charge so free from the marks of age Textbooks may come and go, but "Gray", it seems, remains for ever, a welcome landmark in a shifting landscape

OLD PEOPLE WAITING FOR BEDS

IN 1951 the Hospital Personal Aid Service for the Elderly was set up by King Edward's Hospital Fund to visit in their homes old people who are awaiting admission to hospital The service visits only at the request of the hospital staff, and in their report for 1957 they say that during the year they visited 1765 old people on behalf of 15 hospital management committees On their visits the caseworkers of the service collect information about the patients' home circumstances, which is a useful guide to the hospital both in assessing priority for admission and later in arranging for discharge The visits also ensure that waiting-lists are kept up to date and that the names of patients who no longer want a bed are removed. The service is able to report that since it began its work in 1952 the percentage of patie[illegible] [illegible]ho have to wait over two months for a bed has fallen fro[illegible] 23 to 2, and that in 1957 66% of their patients were a[illegible]ted within a week. The address of the service is New Cr[illegible] General Hospital, Avonley Road, London, S.E.14

FACIAL ECZEMA IN NEW ZEALAND SHEEP

AN important advance in the knowledge of the ætiology of facial eczema has been reported by Dr C P McMeekan from the Government Animal Research Station at Ruakura, near Hamilton where the elusive toxic factor has been identified with the fungus *Stemphylium botryosum*

The disease (writes our New Zealand correspondent) affects mainly sheep, and is almost entirely limited to the North Island, though cattle are also affected and the guineapig can be used for laboratory studies Jaundice and sores on exposed parts of the body—especially around the face—are attributed to liver damage and the circulation of photosensitive breakdown products The liver lesion is essentially a cholangitis affecting the smaller ducts, and when severe can lead to obliteration and fibrosis

The dangerous time of year for outbreaks of facial eczema is autumn, when warm rains encourage the growth of fresh young grass—particularly in the ryegrass area As yet the only useful palliative measure has been to crowd sheep together to prevent their getting too much "toxic" grass, and warnings are issued each season when conditions are thought to be conducive.

Though many people—farmers as well as scientists—have incriminated a fungus or other live product as the causal agent, there has previously been no proof of such a theory For many years research has been predominately chemical and aimed at identifying a toxic substance in grass

The present success followed the observation by a farmhand that a fine cloud rose from his mower when he was cutting the "toxic" grass He found some mycelial growth at the roots of the grass, and later scraped a fine black deposit off the blades of the mower These both gave positive empirical "beaker" tests for toxicity, and cultures of the fungus have yielded an extract which reproduces facial eczema in guinea-pigs and lambs

Much remains to be done In particular it is not known why the fungus is widespread, although the disease is not But the team of four special chemists and pathologists from Great Britain who will reach New Zealand early next year to carry out further research will now have a much more promising task

---

Royal Society of Tropical Medicine and Hygiene

The opening meeting of the session will be held at 26, Portland Place, London, W 1, on Thursday, Oct 16, at 7 30 P M, when Sir Philip Manson-Bahr will give the first Manson oration He will speak on the March of Tropical Medicine during the last Fifty Years

St Mary's Hospital, Manchester

On Friday, Oct 31, at 4 30 P M, at the Clinical Sciences Building, York Place, Manchester, 13, Prof A M Claye will give the Lloyd Roberts lecture His subject will be The Teaching of Obstetrics—New Edition

A New Teaching Hospital

The Minister of Health has announced that he has authorised the Board of Governors of the United Cardiff Hospitals to appoint architects for the new hospital and medical school to be built at Cardiff He understands that the board intends to hold an architectural competition

A City Sponsors Research

The Mayor of New York has announced (*New York Times*, Sept 18, 1958) the creation of the New York City Health Research Council with an initial income, from tax appropriation, of $600,000 The council is to sponsor public and private research, and priority is to be given to problems of ageing, childbirth and infant care, mental illness, accidents, *heart-diseases, environmental hazards, including air pollution* and radiation, and patient [illegible]

New Surgical Block at Guy's

On Sept 19 Lord Nuffield, president of Guy's Hospital, London, laid the foundation stone of its new surgical block

The 11-storey building will have 10 operating-theatres, 14 wards, and maternity, radiotherapy, and casualty departments In all it will have 378 beds It is hoped that it will be ready in 1960 The block will cost about £2¼ million

North Western Thoracic Society

This society will hold its first meeting of the session on Thursday, Oct 16, at 5 P M, in the Clinical Science Buildings, York Place, Manchester, when Dr Robert Coope will give a presidential address on Sundry and Manifold Changes

British Institute of Radiology

The annual congress and exhibition of this institute will be held on Thursday and Friday, Dec 4 and 5, at Church House, Westminster, London, S W 1 The subjects chosen for discussion include subarachnoid hæmorrhage, chronic bronchitis and emphysema, treatment of carcinoma by supervoltage radiation, and radioisotope techniques Further particulars may be had from the general secretary of the institute, 32, Welbeck Street, W 1

Parkes Weber Collection

Dr F Parkes Weber, who is now 95, has presented to the Wellcome Historical Medical Library the collection of manuscript notes, reprints, and case-reports of rare diseases which he has brought together in the course of his career as a physician and medical writer His books, *Rare Diseases and Some Debatable Subjects* (2nd ed, 1947) and *Further Rare Diseases* (1949), were based on a selection of this material A general index to the collection will be prepared by the Wellcome Library, where it may be consulted in due course (together with the original records and rep[illegible]

Dr. Robert Heilig Library
S. M. S. Medical College

International Association of Gerontology

The European clinical section of this society will hold first meeting in Sunderland from Oct 1 to 4 The subje chosen for discussion are genitourinary disturbances in age, ageing and arteriosclerosis with particular reference anticoagulant therapy, and confusional states in the elde Further particulars may be had from the hon secret Dr E Woodford-Williams, The General Hospital, Sunderla

---

The annual dinner of the Glasgow University Graduates in Y shire will be held at Leeds University on Friday, Oct 17 Fur particulars may be had from Mr James Wishart, 33, Manor R Bradford, 1

The London Hospital old students' dinner will be held at Trocadero, Piccadilly, W 1, on Thursday, Oct 9, at 7 45 Tickets (37*s* 6*d*, or 27*s* 6*d* for those qualified less than five ye may be had from Dr R R Bomford, London Hospital, E 1

The annual students' dinner of Leeds School of Medicine wil held on Friday, Oct 31, at 7 30 P M, in the Griffin Hotel, I Lane, Leeds, when Dr F F Hellier will be in the chair

Semipermanent exhibitions will be held at the Institute of Der tology, Lisle Street, London, W C 2, during the winter The f from Oct 1 to 28, by Dr J P O'Brien, will be on the sweat-reten syndrome

The second number of the *Cerebral Palsy Bulletin* (summer, 1 contains the late Dr H C Cameron's last article, in which he cusses spasticity and the intellect As an example of a spastı brilliant intellect he cited Lord Byron, whose lameness Dr Came believed to be due, not to a club-foot, but to spastic paraplegia effectively supported this retrospective diagnosis by contempor descriptions of Byron's gait Copies of the Bulletin (2*s* 6*d*) may *had from the secretary of the society, 28, Fitzroy Square, Lond* W 1

From Monday, Oct 13, the address of the South West Me politan Regional Hospital Board will be 40, Eastbourne Terr London, W 2

CORRIGENDA *Chlorpropamide*—In last week's letter by Dr J Walker (p 641) we erroneously reproduced the start of the sec sentence of the second paragraph as "*43 diabetics had ch promazine* " This should have read "43 patients had ch propamide "

Accidental Hypothermia—In Dr Moylan's letter on this sub last week, a reference to Dr Emslie-Smith's case 7 was inadverte omitted and it should be made clear that Dr Moylan's compari was with this case only His remarks on the inclusion of endogen myxœdema hypothermia under the heading "accidental", simil referred to case 7 only
